December 17, 2019

Abstract

We examine how changes in earnings opportunities abroad affect the regions of origin of international migrants. We leverage plausibly exogenous variation in exchange rate shocks across Filipino migrant destinations due to the 1997 Asian Financial Crisis. These persistent changes in exchange rates generate variation in migrant earnings across origin areas, based on the distribution of migrants across destinations, allowing us to study the impacts on economic outcomes across Philippine provinces. A theoretical framework guides our empirical strategy, generates testable hypotheses, and helps us quantify the channels through which these shocks have long-run consequences. Compiling data over two decades, we examine the long-run consequences of favorable earnings opportunities for migrants. Persistent favorable opportunities lead to more out-migration, and allow households to invest in human capital accumulation. Down the line, these skilled workers are in turn more likely to migrate. Together, these forces generate large long-run improvements in overseas migrant earnings, and in asset accumulation in migrants' home areas.

1 Introduction

How do better earnings opportunities abroad affect the origin areas of migrants? An improvement in migrant earnings opportunities could set in motion a virtuous cycle of investment, local development, and further migration. As existing migrant workers earn more, and new migrants leave to join them abroad, remittance flows to families back home may rise. These remittances could loosen liquidity constraints on investments in education and enterprises. Increases in local aggregate demand could stimulate growth of domestic industries. And a population with higher human capital may be able to seek out higher-skilled, higher-paying work overseas, further magnifying the dynamic gains. On the other hand, there is also the possibility of a vicious cycle. As overseas earnings opportunities improve, increased remittances sent home may increase demand for leisure, reducing labor supply and investment in enterprises. Increased overseas demand for low-skilled work may discourage households from making educational investments. Declines in human and physical capital investments may have long-run negative consequences for home areas. These varied and potentially opposing possibilities make it difficult to predict the long-run consequences of improved migrant earnings opportunities for migrants' origin areas.

In this paper, we examine the impacts of shocks to migrant earnings opportunities on the origin areas of migrants in one of the world's most important international migration source countries, the Philippines. We exploit exogenous variation in migrant earnings across migrant-origin areas driven by the 1997 Asian Financial Crisis exchange rate shocks. Locations across the Philippines had varied exposure to these shocks to migrant earnings, because prior to the crisis they differed in their rates of international migration, and also had varied overseas destinations (whose exchange rate shocks were heterogeneous). Novel administrative data on migrant worker contracts from the Philippine government makes it possible to conduct this study. We study impacts over slightly more than a decade after the shock.

We find that these exogenous increases in migrant earnings have positive impacts on Philippine provinces. Positive migrant earnings shocks stimulate educational investments, raise future migration, and improve the skill levels, occupations, and wages of future migrants. These mechanisms combine to magnify increases in migrant earnings over the next decade. By contrast, we detect no impacts on the domestic economy in origin areas, whether in terms of employment rates or firm outcomes.

The magnitude of impacts is nontrivial. Consider increasing the magnitude of a province's shock to migrant earnings per capita by one standard deviation. Such a shock would increase average years of schooling of 7-18 year-olds by 0.1 years (0.17 standard deviation), and of

college-age individuals by 0.17 years (0.15 standard deviation). Over the next decade, the international migration rate would be higher by 38.7%, and the share of high-skilled overseas jobs would rise by 11.6%.

These changes combine to lead migrant earnings per capita to be higher by PhP 1,263 (0.386 standard deviation of migrant earnings per capita, about 3.4% of per capita income) a decade after the initial shock.¹ Overall, there are improvements in living standards: such a shock increases the average provincial asset index by 0.18 standard deviation.

These empirical findings raise further questions. Of particular interest is the apparent virtuous cycle between education and migration. How much of the long-run earnings gains can be attributed to increased educational investments, leading to more-skilled migration and higher earnings in the future?

We write down a structural model to quantify the mechanisms behind long-run effects on migrant earnings. We start with a gravity model of migration (based on Bryan and Morten (2019); Hsieh et al. (2019); Eaton and Kortum (2002)), and augment it to allow for heterogeneity in skills across workers and occupations. Workers can make educational investments to acquire more skill and enter higher-skilled occupations. Such investments are inhibited by credit constraints, and improvements in migrant earnings help alleviate those constraints. Using data on migration flows and wages at the level of origin-destination dyads, we estimate the wage elasticity of migration, and dyad-level migration costs.

Our parameter estimates and model can rationalize the magnitudes from our reduced-form analysis. We quantify the importance of different channels in determining long-run impacts. We are particularly interested in the education channel: long-run impacts that stem from higher levels of educational attainment in the population of migrant origin areas. We find that about half (50.1%) of the increase in the international migration rate is due to the education channel. When it comes to the overall increase in migrant earnings per capita in the population, 14% can be attributed to the education channel.

This paper relates to a substantial economics literature on the impacts of international migration on migrant-origin areas. Prior work establishes that workers migrating internationally experience substantial income gains, relative to wages in origin areas (Gibson et al., 2010; Clemens et al., 2016), and that improvements in migrant economic conditions have positive impacts on migrant-origin households (Yang (2006, 2008) and the review by Yang (2011)). We examine impacts on economic development outcomes of entire populations of migrant origin areas, not just the source households of current migrants. The focus on

¹All monetary amounts in this paper are in real 2010 Philippine pesos. The exchange rate was 45 pesos to the USD in 2010.

aggregate outcomes of origin areas is relatively rare in the migration literature, owing to substantial challenges in finding plausibly exogenous variation in migration-related independent variables of interest.² The central methodological concern in such an investigation is that migration-related outcomes are, in general, not randomly allocated across localities, so that any observed relationship with development outcomes may simply reflect the influence of unobserved omitted variables.³

A key contribution of our work is to leverage a natural experiment that provides plausibly exogenous variation in migrant earnings across localities, and estimate its effects on long-run local outcomes. The existing literature tends to emphasize that long-run dynamic gains from migration could come from alleviating liquidity constraints on investment in domestic productive enterprises and positive demand effects on domestic industries. We find, by contrast, little evidence of any impacts on domestic economic outcomes. Instead, the main source of dynamic gains is the positive feedback between educational investments and improvements in high-skilled migration and wages in the future. This is a finding, that to our knowledge, has not been reported elsewhere. That said, it is not a niche finding, as it relates to long-run development impacts in one of the most important source countries of international migrant labor, the Philippines. While the Philippines has been a pioneer in regulating and promoting international migrant labor of its citizens, many other developing countries are following its lead. The impacts we find here may therefore very well apply to an increasing array of developing countries where promotion of international labor migration plays a central role in national economic development policy.

Another contribution is to estimate a structural model that quantifies the role of educational investments in yielding dynamic gains in the form of higher-skilled and higher-wage future migration. Our model builds on recent economic geography migration models, as in Lull (2018); Bryan and Morten (2019); Burstein et al. (2018); Lagakos et al. (2019). Our contribution is to model skill acquisition, and differences in migration probabilities and wages by skill level. Furthermore, as we model the role played by exchange rate changes, we explicitly capture the consequences of changes in opportunities at various destinations. We apply such a framework to an international migration setting with novel data. The favorable opportunities generate income gains at home, which can have ambiguous effects on future migration

²Previous studies on the aggregate impacts of international migration on origin areas include Orrenius et al. (2010), Lopez-Cordoba (2005), Adams and Page (2005), Acosta et al. (2008), Dinkelman and Mariotti (2016), Barsbai et al. (2017), Abarcar and Theoharides (2017), Theoharides (2018), and Theoharides (2019). Barham and Boucher (1998) and McKenzie and Rapoport (2010) study impacts on income distribution in migrant home areas. Kinnan et al. (2019) examine impacts of internal migration on origin areas in China.

³For example, areas with higher education levels could send more migrants, and also have better outcomes. Alternatively, areas experiencing a negative shock might send more migrants overseas as a coping mechanism (Bazzi, 2017; Mahajan and Yang, 2019), Mahajan and Yang (2019), so that migration might be negatively correlated with locality outcomes.

(Bazzi, 2017; Clemens, 2014; Angelucci, 2015).

This paper is organized as follows. Section 2 provides background on international migration from the Philippines. Section 3 describes a theoretical framework that generates testable predictions and motivates the empirical framework. Section 4 describes the data used, Section 5 discusses empirical methods. Section 6 reports empirical results, and Section 7 conducts quantification exercises on the importance of various mechanisms. Section 8 concludes.

2 Philippine Migration: Overview

The Philippines was the first country to facilitate temporary overseas contract migration on a large scale. Online Appendix Table A2 shows that in recent decades increasing shares of the Philippine population have migrated, had a household member migrate, or received migrant remittances. The fraction of the population (reported by households in the Census) currently overseas has risen from 0.7% to 1.6% between 1990 and 2010. Over the same period, the fraction of households reporting an overseas migrant member rose from 3.2% to 6.3%. Migrants also sent remittances to more than just their origin household, however: the share of households receiving remittances rose from 17.6% in 1991 to 26.0% in 2009.

Migration from the Philippines is largely temporary and legal, and occurs through licensed and regulated private recruitment agencies. Recruiting agencies legally can charge fees up to one month's wages, but migrants may incur other costs such as travel to Manila, health checks, and passport processing. Overseas temporary contract work is the primary channel through which Filipinos migrate.

Crucially for our identification strategy, Filipinos migrate to a wide variety of destinations, and across provinces, the choice of destination varies substantially. Table A1 shows the top twenty destinations for all Filipino migrants prior to the Asian financial crisis. Other than Saudi Arabia and Japan, no other top destination accounts for more than 10% of migrants. There is also substantial heterogeneity in the wages earned by migrants in different destinations. For instance, migrants in Saudi Arabia earn, on average, 306,000 Philippine pesos (Php) per year, while the figure for migrants to Japan is Php 1.5 million. Within the Philippines, emigration is more prevalent in certain provinces. Table 1 shows that, across provinces, the average international migration rate for 25 to 64 year olds is 2.6%, with a range of 0.0% to 19.5%.

3 Theoretical Framework

Our theoretical framework captures the different channels through which changes in migrant earnings affect households, education investments, migrant flows, and earnings. We use the model to guide our empirical specification, generate testable hypotheses, validate our empirical findings and quantify the importance of underlying channels. Our framework relates to recent quantitative gravity models of the flows of goods and workers, such as Bryan and Morten (2019); Hsieh et al. (2019); Eaton and Kortum (2002). We include the role of education and exchange rate shocks, in order to tease out various pathways.

3.1 Migration Decisions

An individual i 's earnings w_{idost} varies across the province of origin o , the destination country d , their skill level s , and over time t . It depends on migration costs τ_{dot} , exchange rates EX_{dt} , destination specific ability draws q_{id} , and destination specific wage profiles w_{dst} . Since recruitment agencies take a fraction of wages as their fees, workers lose a percentage of their wages as their migration cost. ϵ_{odt} is any unobservable factor that makes migrants from origin o more productive in destination d .

$$w_{idost} = w_{sdt} EX_{dt} (1 - \tau_{dot}) q_{id} \epsilon_{dot} \quad (1)$$

Here, $\tau_{oo} = 0$. Like most of the literature, we assume the ability draw is distributed multivariate Frechet with a shape parameter θ , as in Eaton and Kortum (2002). This parameter determines the dispersion of skills across locations.⁴

$$F(q_1, \dots, q_D) = \exp \left\{ - \left[\sum_{d=1}^D q_d^{-\theta} \right] \right\} \quad (2)$$

Let π_{dost} be the fraction of people of skill s from origin o who choose to work in d . We can derive this share (the details of which are in Appendix D.1) to be:

$$\pi_{dost} = \frac{(w_{dst} EX_{dt} (1 - \tau_{dot}) \epsilon_{dot})^\theta}{\sum_k (w_{kst} EX_{kt} (1 - \tau_{kot}) \epsilon_{kot})^\theta} \quad (3)$$

⁴Abilities may be correlated across locations with a correlation coefficient of ρ . For higher ρ , individuals that have higher ability in location d also are more able in d' . We can then simply re-define $\theta = \frac{\bar{\theta}}{1-\rho}$.

Taking logs, we derive these gravity equations between origin-destination pairs.:

$$\log \pi_{dost} = \theta \log w_{dst} + \theta \log EX_{dt} + \theta \log (1 - \tau_{dot}) + \log \left[\sum_k (w_{kst} EX_{kt} (1 - \tau_{kot}) \epsilon_{kot})^\theta \right] + \theta \epsilon_{dot} \quad (4)$$

3.2 Earnings Shocks and Human Capital Investments

Households choose the amount of schooling S when young, how much to borrow from the future \bar{b} , and the location of work d when older. This location can be the home province o or any foreign country. They maximize their two period utility: $u(c_1) + u(c_2)$.

Period 1 consumption depends on wealth Y (which includes household migrant earnings), the price of schooling p , and how much they can borrow b from period 2. Period 2 consumption is a function of earnings and unresolved period 1 debt with interest R :

$$\begin{aligned} c_{1io} &= Y_{io} - p_o S_{io} + b_{io} \\ c_{2io} &= w_{ido}^m(s) - R_o b_{io} , \end{aligned} \quad (5)$$

where $w_{ido}^m(s)$ is the maximum wage by skill group at the end of the migration decision.

In equilibrium a certain fraction of workers acquire skill. The share of skilled s workers are ℓ_{so} and unskilled u workers are $\ell_{uo} = (1 - \ell_{so})$. Suppose the average years of education for skilled workers is ed_1 and for unskilled is ed_0 , then the average years of education in an origin o is simply: $S_o = \ell_{so} ed_1 + \ell_{uo} ed_0$.

As such, the province-level earnings depends on the baseline distribution of where workers work. Within this setup, it is straightforward to derive that the short-run income change (due to exchange rate shocks) in the origin O depends on the share of migrants at baseline in each destination:

$$\Delta Y_o = \sum_s \ell_{sot} \sum_{k, o=O} \pi_{kost} \overline{w_{kost}} \frac{\Delta EX_{kt}}{EX_{kt}} , \quad (6)$$

where $\overline{w_{dost}}$ is the average wage in destination d for all workers of skill s from origin o , π_{dost} is the share of workers from o working in d , and $\frac{\Delta EX_{kt}}{EX_{kt}}$ is the exchange rate shock. Equation (6) motivates our empirical specifications, where we leverage variation in exchange

rate shocks.⁵

We may expect that changes in migrant earnings help drive investments in human capital at home, for instance, by easing liquidity constraints for households.⁶ For reasonable assumptions on $u(\cdot)$ and w (for instance, $w_{od}(s)$ linear in s , and $u(c)$ continuous, increasing but at a decreasing rate), and for credit constrained households $\bar{b} = 0$, schooling will respond to shocks to migrant earnings: $\Delta S_o = \frac{1}{2p} \Delta Y_o$.

For ease of notation let us define: $\Psi \equiv (ed_1 - ed_0)2p$, which captures the cost of becoming skilled. Then the change in the share of skilled workers in an origin O will be:⁷

$$\Delta \ell_{sOt} = \frac{1}{\Psi} \Delta Y_O = \frac{1}{\Psi} \sum_s \ell_{sot} \sum_{k,o=O} \pi_{kost} \overline{w_{kost}} \frac{\Delta EX_{kt}}{EX_{kt}} \quad (7)$$

3.3 Changes in Migration Flows in Response to the Shock

Migration flows from origin o to destination d depend on the probability of migrating by skill level, and the share of workers in each skill group, where skilled workers are denoted by s , and unskilled workers by u :

$$\pi_{dost} \ell_{sot} + \pi_{dout} \ell_{uot} \quad (8)$$

We can derive the changes in flows between origin o and destination d pairs. This equation is important in that it drives the intuition behind our later analysis. We find that the change in flows can be grouped into two components:

$$\Delta Flow_{sodt} = \underbrace{\Delta \ell_{sot} (\pi_{dost} - \pi_{dout})}_{\text{Education channel in flows}} + \underbrace{\theta (\ell_{sot} \pi_{dost} + \ell_{uot} \pi_{dout}) \frac{\Delta EX_{dt}}{EX_{dt}}}_{\text{Exchange rate channel in flows}} \quad (9)$$

First, skilled workers may have a different migration probability than unskilled workers. If the likelihood of migrating abroad is higher when one is skilled, then an increase in the fraction of skilled workers will raise the flow of migrants abroad. If, on the other hand, most of the demand from abroad is for low skill work, then the probability of migrating may fall when

⁵As we show, from Frechet properties, we know $\overline{w_{dost}} = w_{dst} \pi_{dost}^{-\frac{1}{\theta}} \Gamma \left(1 - \frac{1}{\theta(1-\rho)} \right)$, where Γ is the Gamma function.

⁶In a similar manner, we may model liquidity constraints in investments in local enterprises. As we fail to find supportive empirical evidence for this, we exclude it from the current setup for tractability purposes.

⁷In Appendix D.2 we derive changes to human capital when there are no liquidity constraints or when there is no borrowing possible. For the purposes of our study, we are agnostic about whether the education response is due to easing of liquidity constraints or changing the returns to education. Some combination of the two is possible, as we discuss in the appendix. Additionally, we note that if period 2 consumption is subjectively discounted, say at the rate β , then both the education and skill-share response will be scaled by $\frac{\beta}{1+\beta}$.

one becomes skilled. How skill changes affect flows are captured by the first term, ‘Education channel in migrant flows.’ Rather intuitively, it is the product of two components: (a) the education response to earnings shocks $\Delta\ell_{sot}$, and (b) the skill-differential in the migration probabilities $(\pi_{dost} - \pi_{dout})$.

Second, as exchange rates change favorably, there will be a migration response to this higher compensation. This depends on the Frechet parameter, which pins down the migration elasticity to favorable compensation abroad. Together, the size of the shock $\frac{\Delta EX_{dt}}{EX_{dt}}$, the probabilities of migration $\ell_{sot}\pi_{dost} + \ell_{uot}\pi_{dout}$, and the responsiveness to shocks θ , determine the extent of the change in migrant flows for a given level of education. This is what we call the ‘Exchange rate channel in migrant flows.’

Similarly, the aggregate outflows of migrants from an origin o are simply summed over various destinations, and follow the same intuition:

$$\Delta Flows_{ot} = \underbrace{\Delta\ell_{sot} \sum_k (\pi_{kost} - \pi_{kout})}_{\text{Education channel in flows}} + \underbrace{\theta \sum_k (\ell_{sot}\pi_{kost} + \ell_{uot}\pi_{kout}) \frac{\Delta EX_{kt}}{EX_{kt}}}_{\text{Exchange rate channel in flows}} \quad (10)$$

Later, we use this set up to determine the importance of each channel, and quantify their contributions. We need to estimate not just the change in education $\Delta\ell_{sot}$ and the migration elasticity θ , but also the baseline shares for ℓ and π which determine how the shock in exchange rates EX propagates across different origins. Together, we see how much of the changes in flows can be accounted for by the education and exchange rate channels.

The equations also show that the change in flows are directly functions of the earnings shock. This is true, not just for the exchange rate channel, but also for the education channel. For instance, we know from Equation (7) for $\Delta\ell_{sot}$, that the education channel directly depends on the migrant earnings shock too, in the following manner:

$$\frac{1}{\Psi} \left(\underbrace{\sum_s \ell_{sot} \sum_{k,o=O} \pi_{kost} \overline{w_{kost}} \frac{\Delta EX_{kt}}{EX_{kt}}}_{\Delta Y_o = \text{Migrant Earnings Shock}} \right) \sum_k (\pi_{kost} - \pi_{kout}) \quad (11)$$

3.3.1 Change in Earnings and Consumption Expenditure

The average earnings for the population in an origin O is a weighted average of wages between origin o and destination d , which varies by skill s . The weights are the fraction of the population in each skill group ℓ_{sot} , and the probability of working in destination d given their skill level π_{dost} :

$$\sum_d \ell_{sOt} \overline{w_{dost}} \pi_{dost} + \sum_d \ell_{uOt} \overline{w_{dout}} \pi_{dout} = \ell_{sOt} \left(\sum_d \overline{w_{dost}} \pi_{dost} - \sum_d \overline{w_{dout}} \pi_{dout} \right) + \sum_d \overline{w_{dout}} \pi_{dout} \quad (12)$$

Once again, the change in earnings per capita, will depend on what happens to two different components, driven by: (1) the change in human capital accumulation, and (2) the persistent change in exchange rates, which raises earnings and encourages more flows to favorable destinations. The education channel in earnings can be written as:

$$\Delta \ell_{sOt} \left(\underbrace{\sum_d \overline{w_{dost}} \pi_{dost}}_{\text{avg skilled wage}} - \underbrace{\sum_d \overline{w_{dout}} \pi_{dout}}_{\text{avg unskilled wage}} \right) \quad (13)$$

Here, we know $\Delta \ell_{sOt}$ is a function of the migrant earnings shock from Equation (7). For ease of notational exposition, let us define, $\beta = (\sum_d \overline{w_{dost}} \pi_{dost} - \sum_d \overline{w_{dout}} \pi_{dout})$ as the skill-premium or returns to skill. Together, this allows us to rewrite the education channel contribution to the change in earnings as:

$$\frac{\beta}{\Psi} \left(\underbrace{\sum_s \ell_{sot} \sum_{k,o=O} \pi_{kost} \overline{w_{kost}} \frac{\Delta E X_{kt}}{E X_{kt}}}_{\Delta Y_o = \text{Migrant Earnings Shock}} \right) \quad (14)$$

The remaining component of the change in earnings is the part driven by persistent changes in the exchange rate. This ‘Exchange rate channel in earnings’ picks up the increase in long run earnings, not simply due to the fact that better exchange rates directly increase migrant earnings, but also because they induce a greater flow of migrants (both skilled and unskilled) to places with more lucrative exchange rates. This contribution can be represented by:

$$\left(\sum_k \ell_{sot} \overline{w_{kost}} \theta \pi_{dost} \frac{\Delta EX_{dt}}{EX_{dt}} \right) + \left(\sum_k \ell_{uot} \overline{w_{kout}} \theta \pi_{dout} \frac{\Delta EX_{dt}}{EX_{dt}} \right) = \theta \left(\underbrace{\sum_s \ell_{sot} \sum_{k,o=O} \pi_{kost} \overline{w_{kost}} \frac{\Delta EX_{kt}}{EX_{kt}}}_{\Delta Y_o = \text{Migrant Earnings Shock}} \right) \quad (15)$$

In other words, this is: $\theta \Delta Y$. Once again, the migration elasticity plays an important role in determining long-run earnings. Together, the overall change in earnings is:

$$\left(\frac{\beta}{\Psi} + \theta \right) \Delta Y \quad (16)$$

There is some clear intuition behind this relationship. First, a higher skill-premium β means that as students get more educated (say, as liquidity constraints are eased), the more the rise in earnings. Second, a lower cost of education Ψ means that easing liquidity constraints has a larger impact on the education margin, as more children can easily go to school. These two parameters determine the size of the contribution of the education channel in earnings. Third, a higher migration elasticity θ means that migration flows, and thereby earnings, are more responsive to favorable exchange rates. This last parameter helps determine the importance of the changes in exchange rates in determining long run earnings.

While in the short run, total earnings and expenditures may simply increase by $\Delta c_{1O} = \Delta Y_O$. In the long run, total migrant earnings, and as a result total household expenditures, may increase by an amount greater than the initial gain in income:

$$\Delta (c_{1O} + c_{2O}) = \Delta Y_O \left(1 + \frac{\beta}{\Psi} + \theta \right) > \Delta Y_O \quad (17)$$

We use these derived lessons from our theoretical framework to discipline our empirical analysis, interpret the coefficients of our reduced form estimates, rationalize the magnitudes, and quantify the contribution of each of the different channels discussed.

4 Data Sources

We summarize our data sources here, and provide further details in the Online Appendix Section A. Summary statistics can be found in Table 1.

4.1 Exchange Rate Shock Variables

Two unique administrative datasets from agencies of the Philippine government allow us to calculate the two key province-level variables needed for our analysis: 1) the earnings-weighted exchange rate shock, and 2) baseline (pre-shock) migrant earnings per capita.⁸ The first dataset is from the Overseas Worker Welfare Administration (OWWA), the government agency tasked with ensuring the well-being of overseas migrants and their families. All Filipinos departing on overseas work contracts are required to obtain OWWA membership prior to departure, and OWWA keeps a detailed membership database that includes the migrant's home address in the Philippines. The second dataset, from the Philippine Overseas Employment Administration (POEA), provides data on migrant earnings. POEA is tasked with enforcing regulations related to work contracts of OFWs. In particular, POEA verifies that contracted wages meet minimum wage requirements (see McKenzie et al. (2014) for a detailed discussion) and keeps a database of wages and other contractual information for departing OFWs. Both the OWWA and POEA data include name, date of birth, destination, and gender, and so we match the two datasets using probabilistic matching in order to determine the province of origin for all migrants in the POEA database.

We combine the POEA/OWWA with monthly exchange rate data from Bloomberg LP to construct the exchange rate shock variable. Annual data from World Development Indicators are used to show the persistence of the exchange rate shocks.

4.2 Data on Outcomes

We use POEA/OWWA data from 2007, 2008 and 2009, to look at outcomes in terms of new migrant contracts. Here we focus on new contracts and the occupational distribution of contracts. The POEA/OWWA also categorize each detailed occupational code into broad occupational groups (such as professionals, production workers, service workers), and we use these groups to examine the change in the occupational distribution of new contracts. We also use information on the recruitment agency as recorded by the POEA. Agencies typically recruit from specific provinces, and serve certain destinations. As we show later, the more recruitment agencies serving a province, the more destinations and out-flows of migrants from that region.

Data on child years of schooling in our panel of provinces come from four rounds of the Philippine Census of Population (1990, 1995, 2000, and 2010). The exchange rate shocks

⁸Theoharides (2019) also uses these data.

occurred in 1997, so for each province observation we have years of schooling data for two pre-shock years and two post-shock years. In additional analysis, we create skill shares of workers by classifying them into skilled and unskilled, based on the education distribution.

The Census contains data on ownership of a number of durable goods, access to utilities, housing quality, and land and home ownership. We construct an index of household assets by taking the first principal component of these variables (Filmer and Pritchett (2001)).⁹

The Philippine Census does not ask about employment status in all years, so we use data from the Philippine Labor Force Survey (LFS), quarterly from 1992-2011, to create a panel of labor supply outcomes, including international migration specifically. We examine province-level labor force participation rates for individuals aged 16 and above, and employment rates for children aged 10-15 (for whom labor force participation is not measured). These outcomes are defined as *domestic* labor supply rates, excluding migrants. The survey also allow us to distinguish the class of worker – for instance, whether they are self employed, working in their own household enterprise, or employers themselves. In addition, we examine internal migration rates for working-age individuals.

We use the Annual Survey of Philippine Business and Industry (ASPBI) to study domestic firm production. We obtain a consistent panel of provinces between 1988 and 2015 that consist of manufacturing firms. The survey asks about revenues, exports, inventories, employment, hours worked, and compensation, among other things. The ASPBI aims to cover all provinces in the country.

5 Estimation and Empirical Strategy

5.1 Gravity Equation Parameters θ and τ_{od}

Our gravity equation determines the flows of workers from origin o to d . In Equation (4) the unknown parameters are the migration elasticity θ , and the set of migration costs τ_{od} .

$$\log \pi_{dots} = \theta \log w_{sdt} + \theta \log EX_{dt} + \theta \log (1 - \tau_{odt}) + \log \left[\sum_k (w_{skt} EX_{kt} (1 - \tau_{okt}) \epsilon_{okt})^\theta \right] + \theta \epsilon_{odt} \quad (4)$$

⁹These asset data are only available in the 1990, 2000, and 2010 rounds of the Census. The loadings on the individual variables are obtained from the principal component analysis for the 1990 data, and the resulting loadings are then used to construct an asset index for 2000 and 2010. The principal component loadings can be found in Online Appendix Table A6.

5.1.1 Estimating Migration Elasticities θ

To estimate the Frechet dispersion parameter, θ , we use a few different methods. First, we directly use Equation (4), and argue that the exchange rate shocks are exogenous. As such, the coefficient on $\log EX_{dt}$ identifies θ . We implement this in two different ways by creating our data to be at the origin-destination-skill level, and then simply at the destination-skill level. In the former method we include the origin-by-skill fixed effects and two-way cluster our errors at the origin and destination level. In the latter method, we include the requisite skill fixed effects and cluster our errors at the destination level.

For our second method, we recognize from the Frechet properties that, $E(q_d|d) = \pi_{do}^{-\frac{1}{\theta}} \Gamma$, where $\Gamma = \Gamma\left(1 - \frac{1}{\theta(1-\rho)}\right)$ is the Gamma function. This allows us to derive an earnings relationship to determine θ :

$$\log \overline{w_{dst}} = \log w_{dst} - \frac{1}{\theta} \log \pi_{dst} + \log \Gamma + \epsilon_{dot} \quad (18)$$

As more and more workers from o move to d , this lowers the average wage, since the marginal migrant has lower ability than the first set of migrants. We use earnings data by origin, destination and skill-level of migrants. We include destination and origin fixed effects, in a regression where our main independent variable is the log of flows from origin to destination, and two-way cluster our errors at the origin-destination pair level.

We estimate the models using Poisson pseudo-maximum likelihood (PPML), which assumes that the errors are uncorrelated with the exponential of the regressions. Yet, one may think that ϵ_{dot} is correlated with $\log \pi_{dst}$. To get unbiased estimates, we use an instrumental variables strategy, following Bryan and Morten (2019).¹⁰

Table A5 produces estimates of θ using the different methods. Our estimates of θ lie between 3 and 3.7 across the different estimation procedures. Our IV-PPML estimates are not statistically distinguishable from our PPML estimates of θ . We use the estimate of 3.4 as our preferred estimate, but in sensitivity checks we vary it for values between 2 and 7 when doing our model quantification exercises.

¹⁰We construct a vector of all flows (and squared flows) to a destination from all *other* origins (i.e. excluding flows from the origin of interest). We then use this vector Π_{dst-o} to predict flows from the origin of interest π_{dst} to the destination. Specifically, we create $\log \Pi_{dst-o}$ to be a vector $\{\log \pi_{d1st}, \dots, \log \pi_{dOst}, (\log \pi_{d1st})^2, \dots, (\log \pi_{dOst})^2\}$. And then predict $\log \pi_{dst} = \alpha_1 \log \Pi_{dst-o}$. We then run our 2SLS regression, where the first stage regresses $\log \pi_{dst}$ on $\log \Pi_{dst-o}$, and the second stage implements Equation (18). We do this using IV-PPML with origin, destination and skill fixed effects, and bootstrap our standard errors.

5.1.2 Estimating Migration Costs

In our framework, migration costs help drive the persistence in migration patterns, and thereby the persistence in changes to migrant earnings. We hypothesize that one reason underlying the persistence is the role played by recruitment agencies. As most agencies serve specific destinations, the presence of an agency in origin o that is likely to serve destination d , lowers the cost of migrating to destination d . Furthermore, competition between agencies is likely to lower how much they charge potential migrants, thereby again lowering the cost of migrating. We parameterize migration costs to capture the role played by recruitment agencies, as one possible factor contributing to such costs.

If recruitment agencies do not rapidly spread across origins or destinations, then the distribution of origin-destination flows may be strongly persistent over time (as we empirically show later). This persistence in origin-destination flows may further drive persistence in migrant earnings in the face of changes in exchange rates. We parameterize the migration cost relationship in the following manner:

$$\log(1 - \tau_{dot}) = \lambda_1 \# Rec Agen_{dot} + \lambda_2 HHI Rec Agen_{dot} + \varepsilon_{dot}^1, \quad (19)$$

where $\# Rec Agen_{dot}$ is the number of recruitment agencies in province o that send at least one migrant to destination d , and $HHI Rec Agen_{dot}$ is the Hirschman-Herfindahl Index that captures the competitiveness of the market for sending migrants from o to d .¹¹

We use Equation (19) in conjunction with Equation (4). The migration costs we estimate vary at the od -pair level. In Equation (4), $\theta \log w_{dst} + \theta \log EX_{dt}$ are absorbed by destination fixed effects μ_d , and $\log \left[\sum_k (w_{kst}(1 - \tau_{kot}))^\theta \epsilon_{kot} \right]$ by origin fixed effects, μ_o .

$$\log \pi_{dot} = \mu_o + \mu_d + \theta \lambda_1 \# Rec Agen_{dot} + \theta \lambda_2 HHI Rec Agen_{dot} + \varepsilon_{dot}^2 \quad \text{for } t = T \quad (20)$$

Notice that in Equation (20), we control for both origin and destination fixed effects, and the migration costs are only identified by variation at the $o - d$ pair level. This means that whether the origin is a big city or a small town, or whether the destination is a rich country or a poor country, is not associated with the migration cost estimates.

That recruitment agencies play such a meaningful role in determining migration flows can be seen by the raw data scatter-plot version of Equation (20) in Figure A2. We residualize all the variables purging them of the origin μ_o and destination μ_d fixed effects, and estimate

¹¹If h_{aod} is the share of workers sent by agency a to d , then $HHI_{od} = \sum_a h_{aod}^2$.

the regression separately for 1993, and for the 2007-9 period. In Figure A2 we simply plot the residuals of the main dependent (vertical axis) and independent variables (horizontal axis). While this relationship is not meant to be causal, it quantifies the migration costs for workers who wish to migrate from origin o to destination d .

Figure A2 shows that the relationship between flows and agencies is strong, and also stable over the 16 year period of our study. This stable and important role played by agencies may explain the underlying heterogeneity in origin-destination flows, and the persistence in such flows (and thereby migrant earnings) over time.

5.2 The Migrant Earnings Shock

As we show in Section 3 we expect migrant earnings to increase in the following manner:

$$\Delta Y_o = \sum_s \ell_{sot} \sum_{k,o=O} \pi_{kost} \overline{w_{kost}} \frac{\Delta EX_{kt}}{EX_{kt}} \quad (6)$$

We rewrite this relationship in a way that makes it easier to take to the data. Let us define the baseline population in an origin province (from the 1995 Census) to be Pop_o , and the number of skilled workers in the province L_{so} . Finally, let the number of skilled workers going from origin o , to destination d simply be L_{sdo} . As such, this means that $\ell_{sot} \equiv \frac{L_{sot}}{Pop_o}$, and $\pi_{dost} \equiv \frac{L_{sdot}}{L_{sot}}$. We can rewrite Equation (6) in the following manner:

$$\Delta Y_o = \sum_s \sum_{k,o=O} \frac{L_{sot}}{Pop_o} \frac{L_{skot}}{L_{sot}} \overline{w_{kost}} \frac{\Delta EX_{kt}}{EX_{kt}} = \frac{1}{Pop_o} \sum_s \sum_{k,o=O} L_{skot} \overline{w_{kost}} \frac{\Delta EX_{kt}}{EX_{kt}} \quad (6)',$$

In terms of total migrant earnings for those from origin o and working in destination d , since $w_{dot} \equiv \sum_s L_{sdot} \overline{w_{dost}}$:

$$\Delta Y_o = \underbrace{\frac{\sum_k w_{ko}}{Pop_o}}_{MigEarn_o} \times \underbrace{\frac{\sum_k w_{ko} \frac{\Delta EX_{kt}}{EX_{kt}}}{\sum_k w_{ko}}}_{ERshock_o} \quad (21)$$

We take this specification directly to the data, defining each of the components in the product above in detail. As such, our causal variable of interest is the province-level shock to migrant earnings per capita. This variable is the product of two dimensions of heterogeneity across provinces: baseline (pre-shock) migrant earnings per capita $MigEarn_{p0}$, and the earnings-weighted exchange rate shock $ERshock_p$.

5.2.1 Earnings-weighted exchange rate shock

Because Filipino provinces differ in the destinations of their international migrants (and their corresponding earnings), there was substantial heterogeneity in the earnings-weighted exchange rate shocks experienced by different provinces following the Asian financial crisis. The East Asian Crisis was unexpected on the part of the affected countries themselves as well as financial market analysts (Radelet and Sachs 1998), and so migrants and their home areas should have been surprised by the shock. The crisis led to the devaluation of numerous currencies throughout Southeast and East Asia, including the Philippines'. As a result, the exchange rate vis-a-vis the Philippine peso changed dramatically in many of the key destinations of Filipino migrants. An appreciation of the exchange rate in a given destination provides a positive income shock to Filipino migrants working there; each unit of foreign currency earned abroad would be convertible to more Philippine pesos.

For each destination d , we construct a measure of the change in exchange rates between the twelve months preceding July 1997 and the twelve months preceding October 1998:

$$\frac{\Delta EX_d}{EX_d} = \frac{\text{Average country } d \text{ exchange rate from Oct. 1997 to Sep. 1998}}{\text{Average country } d \text{ exchange rate from Jul. 1996 to Jun. 1997}} - 1 \quad (22)$$

Exchange rate changes for the 20 major destinations of Filipino migrants are presented in Table A1. Migrants in Saudi Arabia, Hong Kong, and the United Arab Emirates experienced positive exchange rate shocks of approximately 50%. Migrants in Malaysia and South Korea actually experienced slightly negative shocks.

We then calculate the average exchange rate shock for a Philippine province, taking into account a province's baseline share of migrant earnings across overseas destinations. Like before, let w_{do} indicate the total annual earnings of migrants from origin province o who are overseas in country d prior to the Asian financial crisis. The weighted-average exchange rate shock for each province o is defined to be identical to the second term in Equation (21):

$$ERshock_o = \frac{\sum_k w_{ko} \frac{\Delta EX_k}{EX_k}}{\sum_k w_{ko}} \quad (23)$$

In other words, the exchange rate shock for a province is the weighted average exchange rate change across those countries, with each country's exchange rate weighted by the fraction of a province's migrant earnings in that country. Table 1 shows that this variable has a mean of 0.410 and a standard deviation of 0.045.

5.2.2 Baseline migrant earnings per capita

We estimate average earnings per migrant in the province using pre-shock contract data, then multiply average earnings per migrant by the number of migrants in each province from the 1995 Census, obtaining estimated total migrant wages for each province. We then divide total migrant wages by the province’s population to obtain a province’s pre-shock migrant earnings per capita, defined as in the first term of Equation (21):

$$MigEarn_o = \frac{\sum_k w_{ko}}{Pop_o} \quad (24)$$

Table 1 shows summary statistics for $MigEarn_o$. The average is Php 4,263, and the standard deviation is Php 3,275.

5.2.3 The shock to migrant earnings per capita

Our causal variable of interest is the province’s shock to migrant earnings per capita: the product of the earnings-weighted exchange rate shock and baseline (pre-shock) migrant earnings per capita. We construct this from the demeaned component variables ($ERshock_o$ and $MigEarn_o$). It has a mean of -0.014, and a standard deviation of 0.129.

Figure 1 displays the spatial distribution of the residual shock to migrant earnings per capita across Philippine provinces (after partialling out baseline migrant earnings per capita and the earnings-weighted exchange rate shock). The shock appears to be evenly distributed across the country. All regions contain provinces with a range of different shock values.¹²

5.2.4 Persistence of exchange rate shocks and migration patterns

There is persistence over time in both the exchange rate shocks and province-level overseas migration patterns. This leads to persistence of the shock to province-level migrant earnings per capita. Online Appendix Figure A1 shows the exchange rates for the top ten destinations for Filipino migrants over time. The Asian financial crisis is denoted by the dashed line in

¹²We explore what correlates with the shock in Online Appendix Table A7. In Column 1, we see that $ERshock_o$ is larger (exchange rate shocks are more positive) for provinces with high baseline migrant earnings per capita, lower baseline years of schooling, lower female employment rates, and higher rural share of population. $MigEarn_o$ (column 2) is higher for provinces with more positive exchange rate shocks, higher share rural, and with higher asset index. For $ERshock_o \times MigEarn_o$, when migrant earnings per capita and the exchange rate shock are not included as RHS variables, there is a statistically significant positive association with years of schooling and female employment, and a negative one with the asset index. When we control for the baseline level of migrant earnings per capita and the exchange rate shock, only the latter is statistically significant (it is negative in sign), while the coefficients on the baseline province characteristics all decline substantially in magnitude, with only average years of schooling being statistically significantly different from zero (and positive in magnitude).

1997, after which there is substantial dispersion of the exchange rates. Notably, the exchange rate shock is persistent through the year 2010. Persistence of exchange rate shocks can also be seen Table A1 (columns 4 and 5).

In Online Appendix B.1, we discuss formal statistical tests of the persistence of the exchange rate shocks as well as the overseas migrant destinations across provinces. There is strong evidence of both types of persistence. The immediate (one-year) exchange rate shocks have a statistically significant relationship with exchange rates up to 13 years after the Asian Financial Crisis (through 2010). In addition, the pre-shock (pre-1997) international migration destination patterns of Philippine provinces have a positive and statistically significant relationship with destination patterns more than a decade after the shock (in 2009).

5.3 Estimating the Impact of Migrant Earnings on Outcomes

To isolate a causal effect, we estimate the impact of province-level shocks to migrant earnings on province-level outcomes using the following regression specification:

$$y_{ot} = \beta_0 + \beta_1 ERshock_o * MigEarn_o * Post_t + \beta_2 ERshock_o * Post_t + \beta_3 MigEarn_o * Post_t + \alpha_o + \gamma_t + \phi_o * Trend_t + \varepsilon_{ot}, \quad (25)$$

where y_{ot} is the outcome variable of interest for province o in period t . $ERshock_o$ is the earnings-weighted exchange rate shock for province o (expression (23) above). $Post_t$ is a dummy variable equal to 1 in July 1997 and after, and zero otherwise. $MigEarn_o$ is annual migrant earnings per capita in the province (based on pre-shock earnings and population). α_o are province fixed effects, γ_t are period fixed effects, and $\phi_o * Trend_t$ is a province-specific linear time trend. ε_{ot} is a mean-zero error term. Year and province fixed effects are crucial, so that estimates are purged of any association between the shocks and time-invariant locality characteristics or province-invariant time period characteristics. The province-specific linear time trend captures long-running linear changes in outcomes that are specific to each province.¹³ Standard errors are clustered at the level of the provinces.¹⁴

The regression specification also includes $ERshock_o$ and $MigEarn_o$ interacted with $Post_t$.

¹³In a few cases (e.g., for migrant earnings), outcome variables are not available for enough time periods to allow inclusion of province-specific linear time trends. In these cases, we instead capture heterogeneity in trends by including a vector of pre-shock (1990) province-level controls interacted with a time trend ($X_{p0} * Trend_t$). The variables in X_{p0} are from the 1990 Census, and are: school attendance rate (ages 7-18), female employment rate (ages 25-64), male employment rate (ages 25-64), share of population rural, asset index, share of individuals (ages 25-64) working in a household enterprise, and population, with the exception of the employment variables which are not available in 1990 and thus calculated from the 1995 Census.

¹⁴For outcomes in the Census data, we define provinces based on 2000 geographic boundaries, resulting in 82 provinces. Outcomes in the LFS data use provinces based on 1990 geographic boundaries, resulting in 77 provinces.

This is important: we do not presume that $ERshock_o$ and $MigEarn_o$ by themselves to be strictly exogenous. The interaction terms with $Post_t$ account for changes from before to after the shock that are related to provinces' exchange rate shocks and their pre-shock migrant earnings. Only the interaction between the province's destination-weighted exchange rate shock and its pre-shock per capita migrant earnings is taken to be exogenous. Therefore, our coefficient of interest is β_1 on the $ERshock_o * MigEarn_o * Post_t$ term. To ease interpretation of coefficients on $ERshock_o$ and $MigEarn_o$, both these variables are demeaned (so they have mean zero) when included in the regression and also when creating the interaction term.

The identifying assumption is that a province's shock to migrant earnings is unrelated to underlying trends in outcome variables over the two decade time period. This is the parallel-trend assumption underlying difference-in-differences empirical approaches. Concerns about differential trends in outcomes across provinces motivates inclusion – whenever possible – of province-specific linear time trends in the regressions. In all results tables, we show coefficient estimates without and with the province-specific linear trends, to gauge the robustness of results to their inclusion.

5.3.1 Human Capital, the Flow of Migrants, and Skilled Jobs

Our model predicts that schooling $\Delta S_o = \frac{1}{2p} \Delta Y_o$ at the origin changes in response to the shocks. We test this hypothesis across different age-groups and genders, where we estimate Equation (25) with years of education as our dependent variable of interest.

With the help of Equation (21) we also know that this should affect the share of skilled workers in origins, in the following manner:

$$\Delta \ell_{sOt} = \frac{1}{\Psi} \Delta Y_O = \frac{1}{\Psi} \underbrace{\frac{\sum_k w_{ok}}{Pop_o}}_{MigEarn_o} \times \underbrace{\frac{\sum_k w_{ok} \frac{\Delta EX_{kt}}{EX_{kt}}}{\sum_k w_{ok}}}_{ERshock_o} \quad (7)$$

We classify the occupations to be high-skill or low-skill based on information of the average years of education by occupation. Figure A5 shows how the distribution of education across person-weighted occupations, where 13 years of education divides the list of occupations into two groups. Occupations where workers have 13 or more years of education on average are assigned to the 'high-skill' category.

Next, we divide the occupations into the three largest categories in descending order of skill: Professional jobs, production jobs, and service jobs. Professional jobs (about 14% of

contracts) are the highest skilled, with a mean monthly salary of Php 1357, while service workers (about 45% of our contracts) on average earn Php 297 a month. Our model predicts that there will be an increase in flows (as the favorable exchange rate changes are persistent), which may shift flows toward high-skill jobs as workers acquire more education (if emigration probabilities are higher for skilled workers). We study the distribution of occupations in the POEA/OWWA data to identify any occupational upgrading.

Furthermore, our model suggests that the changes in migrant earnings will affect the flows of migrants. This can be seen directly from Equations (10) and (11). Better exchange rates drive more migrant flows, and skill upgrading may amplify this further. We test this hypothesis studying the number of new contracts in the POEA/OWWA data.

5.3.2 Long-run Migrant Earnings per capita and consumption

Persistent increases in favorable exchange rates will increase the stock of earnings over time, and the flow of migrants going to places with favorable exchange rates. If the probability of emigrating is higher for skilled than unskilled workers, then the new flow of migrants may be disproportionately skilled work. This would raise the earnings per migrant, and thereby the overall migrant earnings per capita in the long run. In Equation (16), our model predicts that this shock to baseline migrant earnings will increase long-run earnings due to both the increase in human capital accumulation (and thereby occupational upgrading), and the increased migrant outflows to favorable destinations. We test this hypothesis by examining long-run changes to migrant earnings per capita between 1993 and 2009.

These changes should also affect durable consumption in the long run, in the manner that we describe in the model:

$$\Delta(c_{1O} + c_{2O}) = \left(1 + \frac{\beta}{\Psi} + \theta\right) \Delta Y_O = \left(1 + \frac{\beta}{\Psi} + \theta\right) \underbrace{\frac{\sum_k w_{ok}}{Pop_o}}_{MigEarn_o} \times \underbrace{\frac{\sum_k w_{ok} \frac{\Delta EX_{kt}}{EX_{kt}}}{\sum_k w_{ok}}}_{ERshock_o} \quad (17)$$

We use the Census data to examine how durable consumption changes, by creating an asset index for households.

6 Empirical Results

6.1 Migrant earnings and flows of workers

We first show that the shock variable we construct does have a lasting impact on migrant earnings per capita. We estimate regression Equation (25) where the dependent variable is province-level migrant earnings per capita (total migrant earnings divided by province population, in thousands of real 2010 Philippine pesos). There is one pre-shock observation for each province (1993) and three post-shock observations (2007, 2008 and 2009).

These results are in the first row of Table 2, panel (a). The coefficient on the migrant earnings shock is positive and statistically significant across sets of controls. The magnitude of this effect is meaningful. Column 2's coefficient estimate indicates that for each one standard deviation increase in the initial migrant earnings per capita shock, migrant earnings per capita are higher by nearly 1,263 pesos ($9,794 \text{ pesos} \times 0.129$) a decade later. What can account for such a meaningful change? Our theoretical framework guides us in unpacking a few explanations.

First, the shock also appears to have caused an increase in earnings *per migrant*. In the second row of Table 2, panel (a), we show estimated coefficients on the migrant earnings shock where the dependent variable is earnings per migrant. The initial shock to migrant earnings per capita leads to substantially higher earnings per migrant a decade later.

These increased earnings per migrant may reflect a few changes at origin provinces, as suggested by our model. In panel (b), we show that the positive migrant earnings shock led to meaningful increases in the education levels of the population. Our specifications suggest an increase of between 0.075 and 0.17 years for the working age youth in the post shock period for a one-standard deviation increase in the shock. This increased skill share may lead to better paid jobs abroad.

Second, the shock led to an increase in migrant flows abroad. In panel (c) we see an increase in new migrant contracts. Our theory indicates these increased flows are a result of better prospects abroad given the persistent change in exchange rates, and occupational upgrading, as provinces with positive shocks gain more education (as we will show, the high-skilled are more likely to migrate abroad).

Together, the education-driven occupational upgrading and the increased flow in response to persistent favorable opportunities abroad, drive the increase in migrant earnings per capita. In Section 7 we quantify the role played by each of these channels, and study what fraction

of the increase in migrant earnings can be explained by these components.

6.2 Assets

Having established that the increases in migrant earnings persist for at least a decade after the initial 1997 shock, we turn to examining changes in household assets.

We run regressions where the dependent variable in equation (25) is the provincial average household asset index, using asset data from 1990, 2000, and 2010. Results are in Table 2, panel (d). The shock has a positive impact on the household asset index. The coefficient on the shock is positive and meaningful in magnitude.

We also present nonparametric regression plots of the relationship between the asset index and the shock. In Figure 2, we plot the pre-to-post change in assets (average of 2000 and 2010 minus 1990) against the migrant earnings shock. Both the y-axis and x-axis variables are residuals (partialled-out) from regressions on the main effects of the exchange rate shock ($ERshock_o$) and baseline migrant earnings per capita ($MigEarn_o$). The nonparametric regression plot also shows a positive relationship between the change in assets and the migrant earnings shock. The relationship appears approximately linear.

6.3 Schooling

Since the human capital accumulation component is central to our analysis, we examine changes to schooling in detail. As our framework suggests, positive shocks to migrant earnings could loosen financial constraints on investment in children’s schooling (Cox-Edwards and Ureta, 2003; Yang, 2008; Gibson et al., 2011, 2014; Theoharides, 2019), and also change the expected return to education in the population at large.¹⁵ Changes to education levels at home, will in turn affect occupational upgrading and the long-run earnings potential for those at home.

In Appendix Table A8, we present results from estimating regression Equation (25) where the dependent variables are average years of completed schooling for various age and gender groupings. The unit of observation is the province by Census-year.

We find a positive effect for all children age 7-18 (row 1). Looking at narrower age groups

¹⁵As we discuss in Appendix D.2, positive migrant earnings shocks could raise schooling investments overall if the return to education is perceived to rise (Chand and Clemens (2019), Shrestha (2017)). It is also possible to find reductions in schooling if the return to education is perceived to have fallen (McKenzie and Rapoport (2011)).

(Appendix Table A8), we find positive and statistically significant effects for primary-school-aged children (age 7-12) and for young adults (aged 19-24, tertiary schooling age). For lower-secondary (age 13-15) and upper-secondary (age 16-18) children, regression coefficients are also similar in magnitude, but are not consistently statistically significantly different from zero. Results are very similar when we examine impacts on years of schooling separately for girls and boys. Comparing coefficient estimates across columns 1 and 2, results tend to be quite stable (or increasing in magnitude) when province-specific time trends are added to the regression.

Figure 3a, displays a nonparametric regression plot of the relationship between years of schooling for 7-12 year-olds and the shock. We plot the pre-to-post change (average across post-shock years minus average across pre-shock years) against the migrant earnings shock. As in Figure 2, both the y-axis and x-axis variables are residuals (partialled-out) from regressions on the exchange rate shock ($ERshock_m$) and baseline migrant earnings per capita ($MigEarn_{m0}$). The nonparametric regression plot shows a positive relationship between the change in years of schooling and the migrant earnings shock.

We also show a 'placebo' experiment, taking advantage of the fact that we have two observations of pre-shock data for this outcome variable (1990 and 1995). Figure 3b displays a nonparametric regression plot that is analogous to the plot of panel (a), except that the variable on the y-axis is the change in the pre-shock period (1995 minus 1990). This constitutes a partial test of the identification assumption that no differential pre-existing trends exist that are related to the shock. The plot supports this assumption: there does not appear to be a clear positive relationship between the pre-shock change in schooling and the shock.¹⁶

In Table A9 we explicitly test for pre-trends across all these education outcomes by looking at the changes between 1990 and 1995. We fail to reject the null of no differential pre-trends across all our specifications in panel (a) on education outcomes.

6.4 Skills and occupational upgrading

The increase in schooling levels may change the flow and composition of migrants. For instance, workers with more education may find it relatively easier to find work abroad raising migrant flows.¹⁷ These workers may be more likely to work in higher-paying skilled

¹⁶Similar "true" and "placebo" experiments are shown in Online Appendix Figures A3 and A4, for 7-18 year-olds and 19-24 year olds, respectively. The patterns are very similar to those of Figure 3: there is a positive relationship Panel A (true experiment) and no relationship in Panel B (placebo experiment).

¹⁷Our model suggests that this depends on the relative probabilities of skilled and unskilled migrant flows, π_{dost} and π_{dout} respectively.

jobs. Alternatively, workers with more education may have more employment prospects at home, leading to more negatively selected migration following the exchange rate shocks.

For ease of exposition, we classify each detailed occupation code to be either skilled or unskilled. Figure A5 shows two modes that appear around the 13 year mark, and we use 13 years as a threshold to divide the occupations.¹⁸

Panel (a) of Table 3 shows these results for the full population (including migrants) and migrant workers separately. First, it is clear that migrant workers are about twice as likely to be skilled than the general population. The migrant earnings shock increases the share of skilled workers in both the full population and the migrant population, and the coefficients are statistically significant. For the full population, column 2 shows a 0.6 percentage point increase (0.0464×0.129) in the share that is skilled for a one standard deviation increase in the migrant earnings shock. Relative to a mean of 17.3 percent, these magnitudes are meaningful. For the migrant population, the increase is about 4 percentage points – about a 12 percent increase from the baseline mean. These results suggest that the migrant earnings shock had a meaningful impact on skill-upgrading at home.

We use the 1990 and 1995 Census waves to test for pre-trends in these skill-share variables. Panel (a) of Table A9 shows that for both the migrant population and the full population, there are no detectable pre-trends in the share of skilled workers.

Based on our data that link occupations with education levels, we know that service jobs require the least amount of skill. Production jobs usually require some more education, while professionals, are most likely to be skilled. Panel (b) of Table 3 shows the results for migrant contracts in the three large occupation groupings. In the top half of the panel, we look at flows as a fraction of the 1990 province level working-age population. A one standard deviation increase in migrant earnings has a substantial effect on both professional and production worker flows, but no detectable impact on service sector workers. In the lower half of panel (b) we study migrant occupations as a share of all migrant contracts. We find a shift in the share of contracts away from service jobs and toward professional jobs. While the effect on service jobs is imprecisely estimated, the magnitudes are meaningful.

The combination of the Census and migrant contracts data show that migrant earnings shocks are associated with an increase in the population working in skilled jobs and subsequent migrant flows are concentrated in high-paying occupations. This occupational upgrading for migrants may be related to the increase in migrant flows, since (as we show later)

¹⁸Our results are not particularly sensitive to varying this cutoff. Those with 12 years are likely to have a vocational degree. Those with 14 years are likely to have finished college.

skilled workers have a higher probability of migrating abroad. Importantly, the increase in flows, particularly in high-skilled jobs, will increase long-run migrant earnings for regions that received relatively positive shocks.

6.5 Domestic firm production

Positive migrant earnings shocks may allow liquidity-constrained entrepreneurs at home to invest in enterprises, driving firm activity and raising both revenue and employment. We use the ASPBI data to examine changes in manufacturing production, revenue, exports, employment and wages.

Panel (a) of Table 4 shows the results for firm production. We fail to reject the null of no effects across the list of outcomes we look at. There do not seem to be any detectable effects on revenues, exports, inventories, domestic employment, or hours worked. With the caveat that we only look at manufacturing firms, we fail to detect substantial investments in local production in the long run.

In panel (b) of Table 4, we analyze changes to household entrepreneurship. We study whether positive migrant earnings shocks are associated with more small enterprise growth. We use the LFS data which asks about the type of work, and examine a few different versions of entrepreneurial activity: having a private household enterprise, being self-employed, being an employer, and working in family-based employment (either paid or unpaid). We fail to find consistent evidence on increases in household and small-scale entrepreneurship.

6.6 Domestic labor supply

We estimate regression Equation (25) for quarterly province-level labor supply outcomes from Q1 1992 to Q4 2011.¹⁹ In panel (c) of Table 4, the dependent variable in Equation (25) is the share of the adult population in the labor force, for adults (aged 25-64) and young adults (aged 16-24). For children (aged 10-15), we show employment rates (share of population working) as labor force participation is not recorded. Based on the specification that include province specific time trends, we conclude that there is no strong evidence of substantial impacts on domestic labor supply.

¹⁹Positive migrant earnings shocks can cause increases in leisure consumption (reductions in labor supply) due simply to income effects (Hanson (2007), Baird et al. (2018)), or increase labor supply by alleviating constraints on entrepreneurial investments that use household labor (McCormick and Wahba (2001), Woodruff and Zenteno (2007), Mesnard (2004), Taylor et al. (2003), Mendola (2008), Yang (2006)), making the overall effects ambiguous. Informal insurance provided by international migrants could also promote entrepreneurship at home (Yang and Choi (2007)).

Table A10 shows similar results for employment rates of adults (again, after excluding migrants). Both for the group of young adults (ages 16-24) and adults (25-64) we fail to detect substantial changes to domestic employment rates.

It seems that despite the positive earnings shock, there are no long-run detectable effects on domestic employment, entrepreneurship or labor supply. Since the shock does not seem to induce much change in entrepreneurial activity at home, without increases in firm-level demand there may not be much of a change in domestic employment and labor supply. Instead, it seems that the shock-driven earnings increase drives migrant flows abroad, as workers acquire skills and receive high-paying jobs in professional occupations (Table 3).

6.7 Pre-trends, other channels, and selection biases

In Appendix Section C we analyze threats to identification and alternative channels. First, we discuss the possible threats to identification, given that our specifications rely on the interaction between the exchange rate shock, baseline migrant earnings, and a post-shock indicator. Since we condition on each of these components (and their two-way interactions), and on the possibility of different trends over time, any remaining threat would need to be driven by systemic differential trends across provinces that are somehow associated with the interaction between exchange rate shocks and baseline earnings, but not correlated with controls for province-specific trends. To address any remaining concerns we run falsification experiments in our pre-shock period to show that changes in outcomes prior to the shock have no relationship with the future shock to migrant earnings per capita. Our results in Table A9, and Figures 3b, A3b and A4b help support our assumptions of parallel-trends.

We also discuss the possibility of other channels like trade and FDI. Yet, given the lack of effects on firm production and exports (Table 4), and domestic employment (Table A10), we posit that these channels are unlikely to be important. We also address the possibility of selection bias by showing that no detectable effects on internal migration (Table A11).

7 Accounting and Quantification

7.1 Contributions to the change in migration flows

The discussion in Section 3 allows us to determine the contribution of each channel to changes in flows, and thereby long-run earnings:

$$\Delta Flows_{ot} = \underbrace{\Delta \ell_{sot} \sum_k (\pi_{kost} - \pi_{kout})}_{\text{Education channel in flows}} + \underbrace{\theta \sum_k (\ell_{sot} \pi_{kost} + \ell_{uot} \pi_{kout}) \frac{\Delta EX_{kt}}{EX_{kt}}}_{\text{Exchange rate channel in flows}} \quad (10)$$

The first part that contributes to changes in flows comes from the role played by education. If the likelihood of migrating abroad is higher when one is skilled, then an increase in the fraction of skilled workers will raise the flow of migrants. If, on the other hand, the propensity to migrate is higher for the unskilled, then we may get a lower probability of migrating when one becomes skilled.

In Figure A6 we plot the difference in the baseline probabilities to migrate between skilled and unskilled workers. Specifically, we measure the difference between the share of skilled and unskilled workers that migrate abroad. . The figure shows that for every province in the country, the likelihood of becoming an overseas worker is higher when the worker has 13 or more years of education. This suggest that a shift in the skill distribution to more education should theoretically increase the flow of migrants across all provinces.

The contribution of the education channel is the product of two components: (a) the education response to earnings shocks $\Delta \ell_{sot}$, and (b) the skill-differential in the migration probabilities $(\pi_{dost} - \pi_{dout})$. The first component is obtained with the help of a linear fit of the regression shown in panel (a) of Table 3. We use the specification for the full population sample which includes controls, as we consider it to be both what the model requires and empirically conservative. The second component is obtained directly from data and shown in Figure A6. Together these components allow us to predict the rise in migration flows driven by an upgrading of skills.

To estimate the role played by the exchange rate channel, we recognize that as rates change favorably in a persistent manner, there will be a migration response to this higher compensation. This response depends on the Frechet parameter, which pins down the migration elasticity. In Table A5 we estimate θ , and together with the size of the shock we can determine the extent of the change in migrant flows for a given level of education. Again, we measure the shares of skilled and unskilled, and the propensity to migrate abroad by skill group at baseline (in 1990), and use that to weight the exchange rate changes by destination, as in the second part of Equation (10).

Together, the exchange rate and education channel in flows allow us to quantify the predicted change in migration flows. We can validate the structure of our model by comparing the model predicted flows to the simple OLS prediction based on the regression from panel (c)

of Table 2, which we refer to as $\widehat{Flows_{ot}}$. We plot the relationship between these predicted flows in Figure 4a.

The strong upward sloping relationship in Figure 4a indicates that the model does a good job of predicting migration flows. A number of provinces with a high predicted flow that lie above the 45-degree line, suggesting that there may be other changes in those provinces or non-linearities in the empirical relationship between flows and migrant earnings changes.

Finally, we can now quantify the role played by each channel. To do so, we calculate the share of the total regression based predicted flows that are attributable to the education channel. In other words, we measure: $\frac{\Delta \ell_{sot} \sum_k (\pi_{kost} - \pi_{kout})}{\widehat{Flows_{ot}}}$.

Figure 4b plots the distribution of the contribution of the education channel across provinces. On average about half of the increase in migrant flows is attributable to the increased education response.²⁰ We do a similar exercise for the exchange rate channel. This time, measuring: $\frac{\theta \sum_k (\ell_{sot} \pi_{kost} + \ell_{uot} \pi_{kout}) \frac{\Delta EX_{kt}}{EX_{kt}}}{\widehat{Flows_{ot}}}$. On average, about one-fourth of the increase in migrant flows is attributable to the exchange rate channel. The remaining one-fourth is unexplained.

We may not expect to explain the entirety of flows as we are building off of baseline (1990) shares of migration flows, and using the empirically conservative specification from panel (a) of Table 3. Using baseline shares produce conservative predictions in a systematic manner. Using post-shock (but thereby endogenous) measure on the probability of migration flows from the 2000 Census allows us to explain about the entirety of flows.²¹

7.2 Contributions to the change in migrant earnings

The change in earnings per capita, will again depend on what we refer to as: (1) the education channel which captures the change in human capital accumulation, and (2) the persistent change in exchange rates, which raises earnings and encourages more flows to favorable destinations. The education channel in explaining earnings is represented by Equation (13):

²⁰Note that theoretically, the contribution of the education channel may be negative if low-skilled workers had a higher probability of migrating. Yet, we see in Figure A6, that across provinces, the likelihood of migrating abroad is higher for skilled workers.

²¹In the 1990 baseline data, the migration probability for skilled workers was 3.2% and for the unskilled was 0.9%. In the 2000 post-shock data, the migration probability for the skilled was 4.9% and for the unskilled was 1.6%.

$$\Delta \ell_{sOt} \left(\underbrace{\sum_d \overline{w_{dost}} \pi_{dost}}_{\text{avg skilled wage}} - \underbrace{\sum_d \overline{w_{dout}} \pi_{dout}}_{\text{avg unskilled wage}} \right) \quad (13)$$

Here, we know $\Delta \ell_{sOt}$ is a function of the migrant earnings shock from Equation (7), which we again obtain with the help of linear fit of the regression shown in panel (a) of Table 3. We use the conservative result on the full population with controls. The second component is the probability-weighted skill-premium $\beta = (\sum_d \overline{w_{dost}} \pi_{dost} - \sum_d \overline{w_{dout}} \pi_{dout})$. We plot the skill premium $(\overline{w_{dost}} - \overline{w_{dout}})$ at the origin-destination pair level in Figure A7. The median origin-destination pair offers a skill-earnings premium of about 38 percent (about 9.5 percent per year of education), but there is heterogeneity in returns across destinations.²²

The remaining component of the change in earnings is the part driven by persistent changes in the exchange rate, which captures the increase in long run earnings, not simply due to the fact that better exchange rates directly increase migrant earnings, but also because they induce a greater flow of migrants (both skilled and unskilled) to places with lucrative exchange rates. This contribution can be represented by:

$$\left(\sum_k \ell_{sot} \overline{w_{kost}} \theta \pi_{dost} \frac{\Delta EX_{dt}}{EX_{dt}} \right) + \left(\sum_k \ell_{uot} \overline{w_{kout}} \theta \pi_{dout} \frac{\Delta EX_{dt}}{EX_{dt}} \right) \quad (26)$$

A higher migration elasticity θ (measured in Table A5) means that migration flows, and thereby earnings, are more responsive to exchange rate shocks. The other shares ℓ_{sot} and π_{dost} we measure at baseline (1990), multiply them with the wages at baseline $\overline{w_{dost}}$ and $\overline{w_{dout}}$, and use them as weights for the exchange rate change $\frac{\Delta EX_{dt}}{EX_{dt}}$ as in Equation (26).

We add up the predicted earnings estimate due to the education channel and the exchange rate channel, and create a composite measure of predicted increases in migrant earnings per capita. Once again, we can validate the structure of our model by comparing the model predicted earnings per capita to the simple OLS prediction based on the regression from panel (a) of Table 2, which we refer to as $\widehat{Earnings_{ot}}$. We plot the relationship between these predicted flows in Figure 5a.

Like before, we see a strong upward sloping relationship in Figure 5a which indicates that the model does a good job of predicting migrant earnings per capita. Most of predictions

²²These returns would also capture the fact that for many low-skilled occupations there are no migrant opportunities for certain destinations. As such, increases in skill raise earning prospects by raising employment prospects.

are distributed around the forty-five degree line.

To quantify the role played by each channel, we measure the predicted education channel in earnings as a ratio of the regression-predicted increase in earnings per capita. We plot this in Figure 5b. We do a similar exercise for the exchange rate channel in migrant earnings. On average (unweighted by population), the education channel explains about 14% of the increase in earnings, whereas the exchange rate channel explains about 66%. The remaining one-fifth is unexplained. The unexplained portion includes other changes in migrant earnings. For instance, skilled wages may have increased faster over time than unskilled wages, which is something we are conservative about not allowing for.²³

8 Conclusion

Better migrant opportunities abroad may drive more out-migration. Yet, the income earned from better opportunities may drive investments at home, and investments in entrepreneurship may stem the outflow of migrants. This makes the impacts of better opportunities abroad theoretically ambiguous. In our analysis, we find little evidence of firm-level investments at home. Instead, household invest in human capital. In the long-run skill investments drive the occupational upgrading of workers. Perhaps reflecting limited opportunities at home, most gains are in the form of increased migration abroad, higher overseas wages (due to higher-skilled work), and perpetuating the cycle of higher migrant earnings, greater educational investments, and better overseas jobs. Over the long period an initial shock to migrant earnings can raise long-run earnings by a substantially larger amount.

A theoretical framework guides our empirical analysis, and helps us derive variation in migrant earnings from changes in exchange rates. The testable implications of the framework are to do with investments in education, future migrant flows, the occupational composition of migrants, and long-run changes in earnings and consumption. We find that the model helps rationalize the magnitudes of effects, and allows us to quantify the importance of various channels in explaining changes in long-run migrant flows and earnings.²⁴

Together, our results suggest, that investments in skill and occupational upgrading explain a meaningful fraction of future flows and earnings. This helps transform origin provinces over the longer-period. As such, there can be substantial long lasting effects on regions that are

²³An additional reason why our estimates are conservative are to again do with using baseline 1990 shares for migration probabilities.

²⁴To keep the model simple and not unnecessarily cumbersome, we abstract away from modeling firm level investments at home. Empirically, we find no effects on entrepreneurship at home.

fortunate to benefit from changes to migrant earnings.

Our study provides new insights in the literature on the economics of migration. Due to data limitations, it is rare to be able to examine impacts of migrant opportunities on locality development outcomes in the long run. In doing so, we take advantage of a unique natural experiment that provides plausibly exogenous variation in migrant earnings, to isolate the causal effect of a change in migrant earnings.

These findings also provide insights for policy-makers that seek to design migration policies to foster economic development at home. We stress the importance behind understanding the consequences of migration on migrant sending regions, and the impacts of policies that affect migrants' economic prospects on outcomes in origin areas.

Figure 1: Spatial Distribution of Migrant Earnings Shock Across Philippine Provinces

Notes: Figure presents ranges of residual migrant earnings shock (earnings-weighted exchange rate shock times baseline migrant earnings per capita) after partialling-out main effects of earnings-weighted exchange rate shock and baseline migrant earnings per capita.

Figure 2: Change in Provincial Asset Index on Migrant Earnings Shock

Notes: Nonparametric regressions (biweight kernel, bandwidth=0.1, degree=0, pwidth 0.2) of change in residual household asset index (average of 2000 and 2010 minus 1990) on residual migrant earnings shock (earnings-weighted exchange rate shock times baseline migrant earnings per capita). Residuals taken from regression of variable on earnings-weighted exchange rate shock and baseline migrant earnings per capita. Solid line is nonparametric regression estimate. Gray area is 90 percent confidence interval.

Figure 3: Change in Provincial Years of Schooling (of Children Aged 7-12) on Migrant Earnings Shock

(a) True impact: change from pre-shock (1990 and 1995 average) to post-shock (2000 and 2010 average)

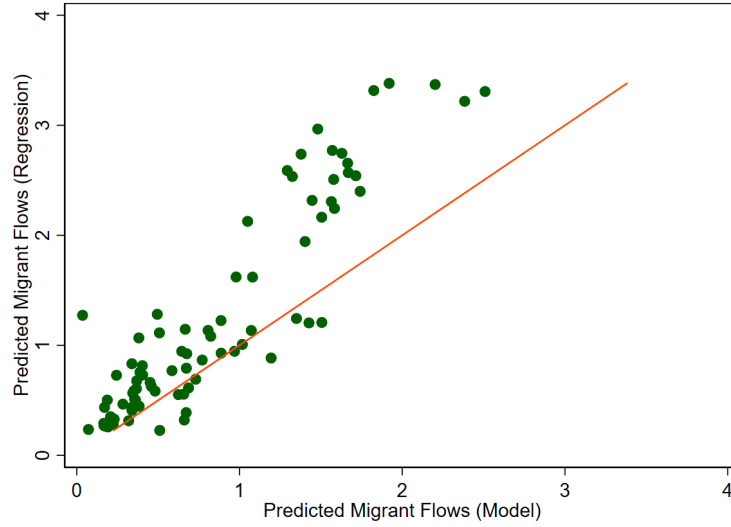

(b) Placebo experiment: change in pre-shock period (1995 minus 1990)

Notes: Nonparametric regressions (biweight kernel, bandwidth=0.1, degree=0), of residual years of schooling on residual migrant earnings shock (earnings-weighted exchange rate shock times baseline migrant earnings per capita). Residuals taken from regression of variable on earnings-weighted exchange rate shock and baseline migrant earnings per capita. Solid line is nonparametric regression estimate. Gray area is 90 percent confidence interval.

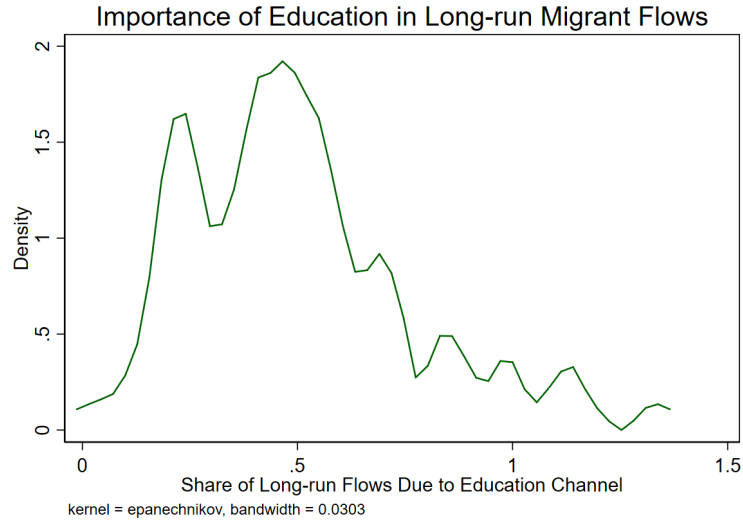

Figure 4: Model Validation and Contribution of Education Channel in Migrant Flows

(a) Model Validation: Predicted migrant flows

Notes: Figure plots the predicted flows of migrants from the regression in panel (c) of Table 2 (vertical axis) vs the predicted flows as determined by the components of Equation (10). The red line has an angle of 45 degrees. Each point represents a province.

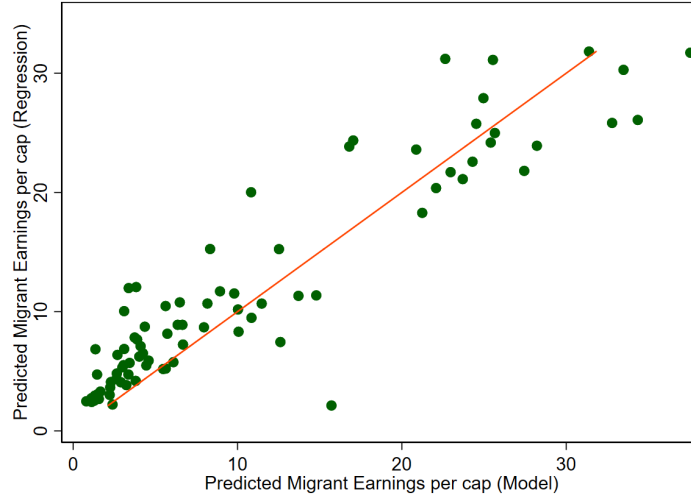

(b) Contribution of Education Channel in Migrant Flows

Notes: Figure plots the contribution of the education channel in predicting migrant flows: $\frac{\Delta \ell_{sot} \sum_k (\pi_{k_{ost}} - \pi_{k_{out}})}{Flows_{ot}}$

Figure 5: Model Validation and Contribution of Education Channel in Migrant Earnings

(a) Model Validation: Predicted migrant earnings per capita

Notes: Figure plots the predicted migrant earnings per capita from the regression in panel (a) of Table 2 (vertical axis) vs the predicted flows as determined by the education and exchange rate components. The red line has an angle of 45 degrees. Each point represents a province.

(b) Contribution of Education Channel in Migrant Earnings per capita

Notes: Figure plots the contribution of the education channel in predicting migrant earnings per capita.

Table 1: Summary Statistics

Shock Variables	Mean	Std. Dev.	Min	Max	Obs.
Shock to Migrant Earnings per Capita ($ERshock_p * MigEarn_{p0}$)	-0.014	0.129	-0.370	0.561	82
Earnings-weighted Exchange Rate Shock ($ERshock_p$)	0.410	0.045	0.204	0.511	82
Migrant Earnings per Capita ($MigEarn_{p0}$)	4.263	3.275	0.838	12.611	82
Household Asset Index	-0.316	0.811	-1.985	3.164	246
Years of Schooling					
Age 7-18	4.880	0.573	3.132	6.123	328
Age 7-12	2.776	0.332	1.758	3.508	328
Age 13-15	6.401	0.619	4.337	7.706	328
Age 16-18	8.196	0.951	4.804	10.355	328
Age 19-24	9.049	1.109	5.259	11.907	328
Share skilled (13 or more years of education)	0.173	0.064	0.021	0.347	328
Share migrants skilled (13 or more years education)	0.348	0.143	0.039	0.763	328
New Migrant Contracts					
Total (% of 1990 population)	0.348	0.269	0.011	1.540	328
Professional Jobs (share of new contracts)	0.139	0.076	0.000	0.606	328
Production Jobs (share of new contracts)	0.343	0.126	0.060	0.735	328
Service Jobs (share of new contracts)	0.145	0.107	0.007	0.809	328
Labor Supply

Labor Force Participation Rate, age 16-24	0.526	0.104	0.157	1.000	6,159
Employment Rate, age 10-15	0.129	0.123	0.000	0.943	6,159
International Migration Rates (share of total population)					
Total, age 25-64	0.026	0.020	0.000	0.195	6,159
Total, age 16-24	0.009	0.011	0.000	0.161	6,159
1990 Population (in 1000s)	735.869	606.314	14.973	2741.496	82

Notes: Unit of observation is province. Shock variables are constructed from POEA/OWWA dataset and other sources (see text). Shock to Migrant Earnings per Capita constructed from demeaned component variables ($ERshock_p$ and $MigEarn_{p0}$). Years of schooling and asset data are from Census (82 provinces; assets available in 1990, 2000, 2010; years of schooling available in 1990, 1995, 2000, 2010). New migrant contracts are from the POEA/OWWA dataset. Labor force participation and migration outcomes are from Labor Force Survey (77 provinces, quarterly data, 1992-2011). Age specific variables are out of the province population in that age group.

Table 2: Impact of Migrant Earning Changes on Migrant Earnings, Assets, Education and Flows of New Migrants

<i>Dependent variable (periods included in regression)</i>	<i>Mean (std. dev.) of dependent variable</i>	<i>Regressions</i>		<i>Number of obs.</i>
		<i>(1)</i> <i>No controls</i>	<i>(2)</i> <i>Controls for heterogeneous province trends</i>	
<i>(a) Migrant earnings (1993, 2007, 2008, 2009)</i>				
Migrant earnings per capita in province	5.254 (4.261)	8.889*** (3.316)	9.794** (4.295)	328
Earnings per migrant	401.431 (317.901)	629.001*** (199.192)	734.578** (314.474)	328

Notes: All regressions include province and year fixed effects. Controls for heterogeneous province trends are: for panel (a), (c) and (d), baseline controls interacted with linear annual time trend; for panel (b), province-specific linear annual time trend. The baseline controls use 1990 data and include: average years of schooling for 7 to 18 year olds, average female employment rate for 25 to 64 year olds, average male employment rate for 25 to 64 year olds, share of households that are rural, the asset index, the share of individuals working in household enterprises, and the population. Panel (a) and (c) use 1993, 2007, 2008, and 2009 data from POEA/OWWA dataset. Panel (b) and (d), are from Philippine Census. Asset index is calculated from the 1990, 2000, and 2010 Philippine Censuses as first principal component of indicators for: radio, tv, refrigerator, phone, running water, electricity, trash collection, uses wood fuel to cook, uses a high quality fuel to cook, flush toilet, house has metal roof, house has brick walls, household owns land, and household owns home. For panel (a) and (c) post equals 1 in 2007-2009, in panel (b) and (d) post equals 1 in 2000 and 2010, and 0 otherwise. Robust standard errors are clustered at the province level. *** indicates significance at the 1% level. ** indicates significance at the 5% level * indicates significance at the 10% level.

Table 3: Impact of Migrant Earning Changes on Skill Share of Workforce

Dependent variable (periods included in regression)	Mean (std. dev.) of dependent variable	Regressions		Number of obs.
		(1) No controls	(2) Controls for heterogeneous province trends	
(a) Share skilled (1990, 1995, 2005, 2010)				
Full population	0.173 (0.0637)	0.0858*** (0.0245)	0.0464* (0.0259)	328
Migrants	0.349 (0.143)	0.344*** (0.0653)	0.313*** (0.0898)	328
(b) Migrant Occupations (1993, 2007, 2008, 2009)				
as a percent of 1990 working-age population:				
Professional	0.049 (0.057)	0.449*** (0.101)	0.410*** (0.092)	328
Production	0.130 (0.136)	0.387** (0.158)	0.446** (0.171)	328
Service	0.145 (0.107)	0.032 (0.136)	0.06 (0.125)	328
as a share of new migrant contracts:				
Professional	0.139 (0.076)	0.416*** (0.136)	0.221* (0.129)	328
Production	0.343 (0.126)	0.008 (0.077)	-0.002 (0.093)	328
Service	0.454 (0.159)	-0.368*** (0.112)	-0.159 (0.115)	328

Notes: All regressions include province and year fixed effects. Controls for heterogeneous province trends are: for panel (a) province-specific linear annual time trend; for panel (b) baseline controls interacted with linear annual time trend. Share skilled defined as having 13 or more years of education in the Census data. Migrant occupations are from the POEA/OWWA dataset. *** indicates significance at the 1% level. ** indicates significance at the 5% level * indicates significance at the 10% level.

Table 4: Impact of Migrant Earnings Shocks on Firm Production and Labor Supply

Dependent variable	Mean (std. dev.) of dependent variable	Regressions		Number of obs.
		(1) No controls	(2) Province- specific linear time trends	
(a) Firm production				
Log total revenue	14.79 (1.527)	-0.306 (0.774)	0.699 (1.091)	1388
Log value of exports	0.264 (0.709)	-0.0272 (0.343)	-0.227 (0.515)	1388
Log total inventories	9.698 (3.079)	0.419 (1.910)	2.139 (2.528)	1388

Log total hours worked	9.541 (2.010)	-0.665 (0.785)	-1.086 (1.666)	1388
(b) Household and small entrepreneurs, adults (aged 25-64)				
Private household enterprise	0.0248 (0.094)	0.007 (0.0097)	0.006 (0.0138)	6159
Self employed	0.300 (0.094)	-0.056 (0.0395)	0.009 (0.0267)	6159
Employer of other employees	0.0326 (0.094)	0.038* (0.0225)	-0.009 (0.0172)	6159
Family employment (paid or unpaid)	0.0909 (0.094)	-0.119*** (0.0380)	-0.051 (0.0442)	6159
(c) Domestic labor supply (no migrants)				
Labor force participation, adults (aged 25-64)	0.763 (0.070)	-0.064* (0.033)	0.021 (0.041)	6159
Labor force participation, young adults (aged 16-24)	0.521 (0.105)	-0.046 (0.064)	-0.077 (0.054)	6159
Employment rates, children (aged 10-15)	0.129 (0.123)	-0.039 (0.067)	-0.033 (0.061)	6159

Notes: All regressions include province fixed effects, year fixed effects, baseline migrant earnings per capita times post, and weighted-average exchange rate shock times post. Regressions in column 2 include province-specific linear time trends. Manufacturing firm production, panel (a), data are from the Annual Survey of Philippine Business and Industry (ASPBI). The sample only includes province-year observations that have more than 3 firms recorded in the year. Employment outcomes and household entrepreneurship data are from the Philippine Labor Force Survey, and cover the years 1992-2011. The unit of observation is the province-quarter-year. Labor force participation rate is share in the labor force out of total population in the age group. Employment rate is share working out of total population in age group. International migrants are excluded in calculation of outcome variables in panel (c). Post equals 1 in 1997, quarter 3 to 2011, and 0 in 1992-1997, quarter 2. Robust standard errors are clustered at the province level. *** indicates significance at the 1% level. ** indicates significance at the 5% level. * indicates significance at the 10% level.

Online Appendix

A Data Appendix

A.1 Migration Data

Calculation of key variables in our analyses (the migrant-earnings-weighted exchange rate shock and migrant earnings per capita from each Philippine province) requires unusual data on migrant earnings and migrant overseas locations by province. To calculate these variables, we obtained two unique administrative datasets from agencies of the the Philippine government. The Philippine Overseas Employment Administration (POEA) is tasked with approving migrant contracts and providing exit clearance. They maintain a rich database on all new contract migrants, including data on name, date of birth, sex, marital status, occupation, destination country, employer, recruitment agency, salary, contract duration, and date deployed. The detailed occupations are also classified into broad occupation categories by the POEA. The Overseas Worker Welfare Administration (OWWA) is responsible for the welfare of overseas workers and their families, and all migrants are required to register with OWWA. OWWA maintains a database that includes migrants' name, date of birth, sex, destination country, date deployed and home address in the Philippines.

To create a dataset that includes migrant wages, destination, and province of origin, we combine the datasets from POEA and OWWA using fuzzy matching techniques (Winkler, 2004) for the years 1993, 2007, 2008, and 2009. In the pre-shock (pre-1997) period, we use only data from 1993 work contracts for this calculation because it has the fewest missing values for migrant origin address in the OWWA data (86% non-missing) of all pre-crisis years (1992-1996). In the post-shock (post-1997) years, we use only the 2007-2009 contract data because in order to create migrant earnings per capita, we later match these data with the 2007 and 2010 Philippine Census, as discussed below. We match the POEA and OWWA data using first name, middle name, last name, date of birth, destination country, sex, and year of departure. We achieve a match rate of 95%.

Using the matched dataset, we then calculate the share of total province-level migrant annual earnings from each destination country in 1993. We aggregate migrant wages in each destination-province, and then divide these destination-province specific wage totals by the total migrant wages for the province. The wage shares are then used to create the earnings-weighted exchange rate shock, and the wage returns to skill. All wages are in thousands of

real 2010 Philippine pesos.

To calculate migrant earnings per capita, we calculate total migrant earnings from the province by multiplying average province earnings in 1993 by the number of migrants in a given province reported in the 1995 Census. Since the POEA data only includes new hires, we used data from the Census to aggregate to total migrant earnings in the province (the Census includes all migrants, not just new hires). We then divide by the 1995 province population, obtaining migrant earnings per capita prior to the 1997 shock. We go through a similar calculation for migrant earnings per capita in 2007, 2008, and 2009. For each year, we calculate average migrant earnings from the POEA/OWWA data. We then multiply by the total number of migrants in the 2007 Census (for 2007 migrant earnings per capita), in the 2010 Census (for 2009 migrant earnings per capita), or the average of the 2007 and 2010 Census (for 2008 migrant earnings per capita).

We use the POEA/OWWA classification of broad occupation categories to create migration rates by occupation. There are three broad categories we examine: (1) Professional occupations include performing artists, engineers, medical professionals and teachers, among other professions. (2) Service workers are usually caretakers and caregivers, cooks and waiters, and domestic helpers among other occupations. (3) Production workers comprise of brick-layers and carpenters, electrical workers, and plumbers among other occupations. Together, these three categories cover about 94 percent of migrant contracts.

There is one caveat with using the home address variable to calculate province-level wages: the home address variable in the OWWA data includes municipality, but not province. Out of 1630 municipalities in the Philippines, 332 have ambiguous names that are used in more than one province. This accounts for between 10 and 19% of migration episodes depending on the year. Thus, to calculate province-level variables, we assign municipalities with such duplicate names their population share of the total wages across municipalities with the same name. In addition, a small minority of migrants fail to report municipality in the OWWA data (14% in 1993). Theoharides (2019), who also uses the matched POEA/OWWA dataset, shows that municipalities appear to be missing at random, so we simply drop observations with missing municipalities from our analysis.

A.2 Census Data

We created a panel of schooling and asset outcomes using the 1990, 1995, 2000, and 2010 Philippine Census of Population from the Philippine Statistical Authority. Each census

wave includes 100% of the non-institutionalized Philippine population. In each round of the census, we take the average within the province across all households (for the asset index) or individuals within age groups (for years of schooling).

To study the impact on the skill composition of jobs, we use information on occupations and educational attainment from the Survey of Overseas Filipinos (SOF). The survey ask families about the education and occupations of household members, and we calculate an average education level for each occupation in the Philippine Standard Occupational Classification (PSOC), which we match to the Census data.

A.3 Labor Force Survey Data

Data on employment rates are from the 1992-2011 quarterly Philippine Labor Force Survey (LFS). The LFS is widely used by the Philippine Statistical Authority (PSA) to calculate official government statistics, such as employment statistics, as well as by academic researchers. The data are collected in January, April, July, and October. We have five years of pre-shock data, and 14 years of post shock data. The first two quarters of 1997 are assigned to the pre-shock period, while the latter two quarters of 1997 are considered post-shock. Each survey round includes approximately 200,000 individuals and 44,000 households, and includes sampling weights.²⁵ One-quarter of households are rotated out of the sample in each quarter, and the data are repeated cross-sections.

Labor force participation, international migration status, and employment-related variables are available for all household members aged 15 and above, while employment status is available for individuals age 10 and above. Individuals are defined as employed if they did some work, even for an hour, during the past week. Households are asked about migrant members and their demographics, but employment status is not asked about migrant members. We assume that all household members who are currently overseas on a work contract are employed. We calculate the employment rate by dividing by the province population in a given age-gender group. We also create variables for the share of employed workers engaged in each employment class out of the province population. Labor supply outcomes in Table 4 exclude international migrants in the rate calculations.

²⁵More technical details on the LFS can be found here: <https://psa.gov.ph/content/technical-notes-labor-force-survey-lfs>

A.4 Firm Production Data

Data on firm revenue, exports, inventories, employment, hours and compensation are from the Annual Survey of Philippine Business and Industry (ASPBI). This is a sample-survey covering the entire country. We obtain data between 1988 and 2015 only for province-year observations that had more than 3 manufacturing firms in their survey. This means that at most we have information for about 76 (out of 82) provinces, and some years have fewer observations. Yet, to the best of our knowledge, this is the longest detailed comprehensive panel of firm activity. The survey uses the official List of Establishments (LE) as their sampling frame. An establishment is the unit of enumeration in the survey, defined to be an “economic unit under a single ownership or control.” The sampling design is stratified systematic sampling with employment size-group as the stratification variable. In our analysis, we use sample weights when examining the ASPBI data. Unweighted regressions produce qualitatively similar results.

Our main variables of interest include employment (the number of workers on payroll in November of the survey year) and number of hours workers by production workers (including wait time and overtime, but excluding sick and vacation leave). Revenue includes cash received for goods sold and services rendered, while inventories refer to the stock of goods by and under the control of establishment regardless of where the stocks are located.

B Additional Empirical Analyses

B.1 Persistence of exchange rate shocks and migration patterns

We present here empirical analyses of the persistence of exchange rate shocks and of overseas migration destination patterns from Philippine provinces.

We first provide evidence of long-run persistence of the exchange rate shocks generated by the Asian Financial Crisis. In Online Appendix Table A3, we test whether the initial (short run) exchange rate shock persists over three and thirteen years after the shock. In Columns 1 through 3, we regress the three-year (1997-2000) change in the exchange rate on the one-year (1997-1998) change in the exchange rate. The shocks are persistent across various country subsamples (all countries, as well as only countries with large numbers of Filipino migrants). Columns 4 through 6 show the correlation of the 13-year (1997- 2010) and one-year exchange

rates, showing that the exchange rate shocks are also highly persistent over this longer time window.

Also crucial to the analysis is that the destinations of migrants from particular provinces (and thus the locations of their overseas earnings) show persistence or “stickiness” over time. We provide evidence of persistence in origin-province/overseas-destination in Online Appendix Table A4. In Online Appendix Table A4, we first show that total province-level international migration rates are highly persistent: when regressing post-shock (2000 or 2010) migration rates on the initial (1995, pre-shock) migration rate, the coefficient on the initial migration rate is highly statistically significant and the regression with this single RHS variable has a very high R-squared (close to 0.8). Online Appendix Table A4 then tests persistence of specific overseas destinations by province. We run one regression for each of the top 20 pre-shock overseas destinations, regressing the share of the province’s population migrating to the destination in 2009 on the corresponding share in 1995. Each row presents the coefficient on the 1995 share. The positive and statistically significant coefficients indicate strong persistence in overseas destinations at the province level: knowing a province’s pre-shock migrant destination pattern has strong predictive power for its post-shock destination pattern. While not every coefficient in this set of 20 is statistically significant at conventional levels (three are not), a test of joint significance of these 20 coefficients rejects the null of no statistical relationship (p-value<0.001).

C Details behind pre-trends, other channels, and selection biases

In this section, we provide additional discussion and empirical analyses to address key concerns related to causal identification.

C.1 Omitted variable bias

Most prominently, there are concerns of omitted variable bias: third factors could be correlated with the shock and changes in key outcomes. To address omitted variable concerns, all our regression specifications focus only on the *interaction* between ER shock and baseline migrant earnings per capita as the right-hand-side variable of interest. Second, we give the most weight to regression specifications that include province-specific linear time trends. In all results tables, we directly compare coefficient estimates from regressions that do not

(column 1) and do (column 2) include these strong controls for heterogeneity in time trends across provinces; coefficient estimates are stable across these specifications for most key outcomes.

In addition, for most outcomes we can run “placebo” experiments in the pre-shock period to show that changes in outcome prior to the shock have no relationship with the future shock to migrant earnings per capita. This is a partial test of the parallel-trend assumption underlying difference-in-differences.²⁶ In Online Appendix Table A9 we present coefficient estimates from placebo experiments.²⁷ We keep only observations prior to the June 1997 shock, and partition the pre-shock observations in to an earlier “control” period and a later “false treatment” period. We run regressions where $Post_t=1$ in this “false treatment” period, and 0 otherwise. We also show non-parametric relationships for different education outcomes in the pre-period in Figures 3b, A3b and A4b. No patterns emerge in this analysis that mirror our main results; trends in key outcome variables in the pre-1997 period do not appear to be related to the size of their (future) shocks to migrant earnings per capita. We take this as support of validity of the parallel trend assumption.

C.2 Channels other than migrant earnings

A key question is whether the shock variable we construct affects outcomes only via its effect on migrant earnings, or whether other channels might be operative. In particular, trade or foreign direct investment (FDI) patterns (between Philippine provinces and overseas destinations) might reflect migration patterns. It is imaginable that positive shocks to migrant earnings per capita might be collinear to some degree with shocks to domestic earnings due to increased trade and FDI. Our results are inconsistent with trade- and FDI-mediated effects, however, since the shock does not lead to increases in domestic employment rates, nor the value of firm production (Table 4). Indeed, we directly estimate the effects on exports for manufacturing firms in Table 4 and fail to find any detectable changes. In Online Appendix Table A10, we present impacts on employment rates (share of population working) of adults (age 25-64) and young adults (age 16-24), in total and by gender.²⁸ Coefficients in nearly all regressions are small in magnitude (and actually negative for young adults) and not statistically significantly different from zero.²⁹

²⁶Data are not available for us to be able to run these placebo experiments for the household asset index (only one pre-shock year is available, the 1990 Census), and migrant contracts (only available pre-shock year is 1993).

²⁷These complement the nonparametric plots of placebo experiments in section 6.3.

²⁸In Table 4, discussed previously, we presented regressions for labor force participation rates in these age groups. Impacts on employment rates for children (age 10-15) were already shown in Table 4.

²⁹The exception is the negative and statistically significant coefficient in the regression for male adults, which declines to zero and loses statistical significance when province-specific linear time trends are added to the regression in column 2.

C.3 Selection bias

Finally we address the possibility of selection bias: changes in the composition of households or individuals across rounds of data (since we have a panel of localities, not a panel of households or individuals). We check for the possibility of selection bias via internal migration by examining the impact of the migrant earnings shock on internal migration rates. Results are in Online Appendix Table A11. We find no large or statistically significant relationship between internal migration and the shock.

D Model Derivations

D.1 Deriving share of flows from o to d

Wages for workers are as defined in the text, to be:

$$w_{iodst} = w_{sdt} EX_{dt}(1 - \tau_{odst})q_{id}\epsilon_{odt} \equiv \widetilde{w_{dost}q_{id}} \quad (27)$$

Workers will pick the destination with the highest value of $w_{iodst} = \widetilde{w_{dost}q_{id}}$. The probability that they pick destination 1 is given by:

$$\begin{aligned} \pi_{1ost} &= Pr [\widetilde{w_{1ost}q_1} > \widetilde{w_{d'ost}q_{d'}}] \quad \forall d' \neq 1 \\ &= Pr \left[q_{d'} < \frac{\widetilde{w_{1ost}q_1}}{\widetilde{w_{d'ost}}} \right] \quad \forall d' \neq 1 \\ &= \int \frac{dF}{dq_1} (q_1, \alpha_1 q_1, \dots, \alpha_D q_D) dq_1 \end{aligned} \quad (28)$$

where we define $\alpha_d \equiv \frac{\widetilde{w_{1ost}}}{\widetilde{w_{d'ost}}}$. We assume that the abilities are distributed with the following Frechet distribution:

$$F(q_1, \dots, q_D) = \exp \left\{ - \left[\sum_{d=1}^D q_d^{-\theta} \right] \right\} \quad (29)$$

So the derivative of the CDF is given by:

$$\frac{dF}{dq} = \theta q^{-\theta-1} \exp \left\{ - \left[\sum_{d=1}^D q_d^{-\theta} \right] \right\} \quad (30)$$

This derivative evaluated at $(q_1, \alpha_1 q_1, \dots, \alpha_D q_D)$, allows us to determine the probability of

choosing destination 1:

$$\begin{aligned}
\pi_{lost} &= \int \theta q^{-\theta-1} \exp \left\{ - \left[\sum_{d=1}^D (\alpha_d q)^{-\theta} \right] \right\} dq \\
&= \frac{1}{\sum_{d=1}^D \alpha_d^{-\theta}} \int \left(\sum_{d=1}^D \alpha_d^{-\theta} \right) q^{-\theta-1} \exp \left\{ - \left[q^{-\theta-1} \left(\sum_{d=1}^D \alpha_d^{-\theta} \right) \right] \right\} dq \\
&= \frac{1}{\sum_{d=1}^D \alpha_d^{-\theta}} \int dF(q) \\
&= \frac{1}{\sum_{d=1}^D \alpha_d^{-\theta}} \cdot 1 \\
&= \frac{\widetilde{w_{lost}^\theta}}{\sum_{d=1}^D \widetilde{w_{dost}^\theta}}
\end{aligned} \tag{31}$$

The third line comes from the properties of the Frechet distribution, where we know that the term in the integral of the second line is simply the PDF with a shape parameter θ , and a scale parameter $\sum_{d=1}^D \alpha_d^{-\theta}$. Expanding on the definitions for $\widetilde{w_{dost}^\theta}$, and including the subscripts, we have:

$$\pi_{dost} = \frac{(w_{dst} EX_{dt} (1 - \tau_{odt}) \epsilon_{odt})^\theta}{\sum_k (w_{kst} EX_{dt} (1 - \tau_{okt}) \epsilon_{okt})^\theta} \tag{32}$$

D.2 Extensions on Education Responses

Non Credit Constrained Households and Changes in Returns: Non constrained households may also respond to exchange rate shocks. Exchange rate shocks may not change the returns to education as they change both the educated and non-educated wage. For those who are not constrained, we derive that for a cost of education $= p_1 S + p_2 S^2$, the optimal amount of schooling does not depend on Y , but only on the returns to education:

$$S_i^u = \frac{w'(s)_d (1 - \tau_{dost}) EX_{dt} q_{id} - p_1}{2p_2} \tag{33}$$

where S_i^u are the years of schooling for unconstrained households. The average education levels of non-constrained households from origin o to destination d are:

$$S_{od}^u = \frac{w'(s)_d (1 - \tau_{dost}) EX_{dt} \pi_{dot}^{\frac{-1}{\theta}} \Gamma - p_1}{2p_2} \tag{34}$$

And the average change in education for unconstrained households from origin o is:

$$S_o^u = \sum_d S_{od} \pi_{dot} = \sum_d \frac{w'(s)_d (1 - \tau_{dost}) EX_{dt} \pi_{dot}^{\frac{-1}{\theta} + 1} \Gamma - p_1}{2p_2} \quad (35)$$

Since $\frac{\Delta \pi_{dot}^{\frac{-1}{\theta}}}{\Delta EX_{dt}} = -\frac{\pi_{dot}^{\frac{-1}{\theta}}}{EX_{dt}}$, we know that:

$$\Delta S_o^u = \sum_d \frac{w'(s)_d (1 - \tau_{dost}) \theta \pi_{dot} \Gamma}{2p_2} \frac{\Delta EX_{dt}}{EX_{dt}} \quad (36)$$

If δ fraction of the population is credit constrained, then the education response will also depend on δ . Notice that for unconstrained households to respond, students must also expect the exchange rate shocks to be permanent.

Constraints on borrowing from future: Setting $\bar{b} = 0$ represents completely constrained households. For partially binding credit constraints., we know $\Delta S = \frac{-R\bar{b}}{2p\gamma_d(1-\tau_{od})q_{id}EX_{td}2} \frac{\Delta EX_{dt}}{EX_{dt}}$.

E Additional Tables and Figures

Figure A1: Exchange Rate Shocks Due to 1997 Asian Financial Crisis

Notes: Data are from World Development Indicators. Annual average exchange rates are in units of foreign currency per Philippine peso, normalized to 1 in 1990, for key destinations of Philippine labor migrants. Vertical dashed line indicates 1997 (year of the Asian Financial Crisis).

Figure A2: Migrant Flows at Recruitment Agencies at the Origin-Destination Level

(a) Migrants Flows and # of Agencies 1993

(b) Migrant Flows and HHI of Agencies 1993

(c) Migrants Flows and # of Agencies 2007-9

(d) Migrant Flows and HHI of Agencies 2007-9

Notes: Figures plot the relationship between Log(Number of Overseas Foreign Workers (OFWs)) on the vertical axis recruitment agencies on the horizontal axis. In panel (a) and (c) we plot the Log(Number of Recruitment Agencies) on the horizontal axis. In panel (b) and (d) we plot the Log(Hirschman-Herfindahl Index of Agencies) on the horizontal axis. Panel (a) and (b) are for 1993, whereas panel (b) and (d) are averaged over the 2007-9 period. The data are at the origin-destination pair level, and all variables are residualized by origin μ_o and destination μ_d fixed effects.

Figure A3: Change in Provincial Years of Schooling (of Children Aged 7-18) on Migrant Earnings Shock

(a) True impact: change from pre-shock (1990 and 1995 average) to post-shock (2000 and 2010 average)

(b) Placebo experiment: change in pre-shock period (1995 minus 1990)

Notes: Nonparametric regressions (biweight kernel, bandwidth=0.1, degree=0), of residual years of schooling on residual migrant earnings shock (earnings-weighted exchange rate shock times baseline migrant earnings per capita). Residuals taken from regression of variable on earnings-weighted exchange rate shock and baseline migrant earnings per capita. Solid line is nonparametric regression estimate. Gray area is 90 percent confidence interval.

Figure A4: Change in Provincial Years of Schooling (of Children Aged 19-24) on Migrant Earnings Shock

(a) True impact: change from pre-shock (1990 and 1995 average) to post-shock (2000 and 2010 average)

(b) Placebo experiment: change in pre-shock period (1995 minus 1990)

Notes: Nonparametric regressions (biweight kernel, bandwidth=0.1, degree=0), of residual years of schooling on residual migrant earnings shock (earnings-weighted exchange rate shock times baseline migrant earnings per capita). Residuals taken from regression of variable on earnings-weighted exchange rate shock and baseline migrant earnings per capita. Solid line is nonparametric regression estimate. Gray area is 90 percent confidence interval.

Figure A5: Average Years of Education by Occupation

Notes: Figure plots the density of the average years of education by occupation for 1993 and the 2007-9 period.

Figure A6: Skilled-Unskilled Migration Probabilities

Notes: Figure plots a binned histogram of the difference in migration probabilities by skill, across provinces in 1990. We calculate the share of the skilled population that in the age-group 25-64 that is an overseas worker in destination d to be π_{dos} . We similarly do this for unskilled workers in π_{dou} . We then aggregate the difference across destinations, and plot $\sum_k (\pi_{kos} - \pi_{kou})$.

Figure A7: Wage skill-premium among migrants

Notes: Figure plots the distribution of $\overline{w_{dost}} - \overline{w_{dout}}$ at the origin-destination pair level

Table A1: Top 20 Locations of Filipino Migrants Prior to Asian Financial Crisis

Destination	% of Total	Average Annual Earnings (000, Real 2010 Php)	Exchange Rate Shock (June 1997- Oct 1998)	Exchange Rate Shock: 2000	Exchange Rate Shock: 2010
Saudi Arabia	41.85	305.93	0.52	0.69	0.72
Japan	16.09	1457.57	0.32	0.70	1.13

Total	100.00				

Notes: Average annual earnings (in thousands) calculated using data from POEA and OWWA in 1993 and is based on 269,990 new migrant contracts in 1993. "Other" includes all migrant destinations outside the top 20 (142 destinations). Exchange rate shock is change in Philippine pesos (Php) per local currency unit prior to the Asian Financial Crisis. The change is defined as the fractional change between July 1996-July 1997 and October 1997-September 1998 (e.g., 10% appreciation is 0.1). The exchange rate shock in 2000 and 2010 are defined as the fractional change in the exchange rate between 2000 and 1997, and 2010 and 1997 respectively. Sources: POEA, OWWA, World Development Indicators.

Table A2: Share of Households with Migrant Connections

<i>Year</i>	<u>Migrants as % of population</u>	<u>% of households with a migrant member</u>	<u>% of households receiving remittances</u>
1990	0.7%	3.2%	
1991			17.6%
1994			19.8%
1995	1.1%	5.0%	
1997			17.3%
2000	1.3%	5.2%	18.1%
2003			20.7%
2006			23.3%
2009			26.0%
2010	1.6%	6.3%	

Source: Authors' calculations from the Philippine Census (1990, 1995, 2000, and 2010) and the triennial Family Income and Expenditure Survey (FIES) from 1991-2009 inclusive. Migrants as % of population is number of individuals reported as migrants divided by total population in Census. % of households with a migrant member is fraction of all households reporting a migrant member in Census. % of households receiving remittances is share of households receiving remittances from overseas (not necessarily from a household member), from FIES (nationally representative survey of households).

Table A3: Persistence of Exchange Rate Shock

	<u>2000 Exchange Rate Shock</u>			<u>2010 Exchange Rate Shock</u>		
	All	Destinations	Destinations	All	Destinations	Destinations
	destinations	with >1000	with >5000	destinations	with >1000	with >5000
	(1)	migrants	migrants	(4)	migrants	migrants
1997-1998 exchange rate shock	1.194*** (0.068)	1.310*** (0.169)	0.840*** (0.117)	1.191*** (0.103)	1.034*** (0.316)	0.511*** (0.179)
N	163	41	25	163	41	25
R2	0.746	0.642	0.593	0.319	0.192	0.088

Notes: Results from regressions of the exchange rate shock through 2000 or 2010 on the 1997-1998 exchange rate shock. Reported coefficients are the coefficient on the 1997-1998 exchange rate shock variable. Exchange rate shocks are defined as Philippine pesos per local currency unit exchange rate in a given year, divided by the 1997 exchange rate minus 1. Robust standard errors are in parentheses. *** indicates significance at the 1% level. ** indicates significance at the 5% level * indicates significance at the 10% level.

Source: POEA, OWWA, and Census.

Table A4: Persistence of Total OFW Rate

Panel A: Persistence of Total OFW Rate

	2000 Migration Rate	2010 Migration Rate
	(1)	(2)
1995 Migration Rate	0.740*** (0.034)	0.977*** (0.055)
N	82	82
R2	0.779	0.797

Notes: The unit of observation is the province. Migration rates are the number of migrants in province j out of the total population in province j. Outcome variables are reported in the column headings. Robust standard errors are in parentheses. *** indicates significance at the 1% level. ** indicates significance at the 5% level * indicates significance at the 10% level.

Panel B: Persistence of Migrant Shares Over Time

Bahrain	0.796*** (0.161)
Brunei Darussalam	0.209** (0.095)
Guam	1.149*** (0.157)
Hong Kong	0.885*** (0.072)
India	0.453 (0.584)
Italy	0.466*** (0.031)
Japan	0.027*** (0.005)
Kuwait	0.642 (0.581)
Lebanon	-0.000 (0.000)

Malaysia	0.046*** (0.013)
Northern Mariana Islands	0.022*** (0.004)
Oman	0.725*** (0.271)
Qatar	2.573*** (0.442)
Saudi Arabia	0.698*** (0.128)
Singapore	0.856*** (0.311)
South Korea	0.034** (0.013)
Taiwan	0.419*** (0.107)
United Arab Emirates	1.521*** (0.308)
United States	0.212*** (0.029)
<i>P-val.: Joint signif. of all coeffs.</i>	<i>0.000</i>

Notes: The unit of observation is the province. N=82. Reported coefficients are from regressions of the number of migrants from province j going to a given destination in 2009 divided by the population in province j regressed on the the number of migrants from province j going to a given destination in 1995 divided by the population in province j. Results are reported for the top 20 pre-shock migrant destinations. Robust standard errors are in parentheses. Bottom row of the table reports the p-value on a F-test of joint significance of the migrant shares in 1995 from a seemingly unrelated regression (SUR) model. *** indicates significance at the 1% level. ** indicates significance at the 5% level * indicates significance at the 10% level.

Table A5: Estimating θ using Poisson Pseudo-maximum Likelihood

	Change in Migrant Flows		Earnings	
Log(EX Rate Change)	3.424*	3.024*		
	(1.808)	(1.748)		
Log(Migrants)			-0.317*	-0.268**
			(0.168)	(0.113)
Observations	23,127	258	7,684	7,282
Specification	Origin-Dest-Skill	Destination-Skill	PPML	IV PPML
Clusters	Origin Destination	Destination	Origin Destination	Bootstrap
Fixed Effects	Origin x Skill	Skill	Origin Destination Skill	Origin Destination Skill
Theta			3.155*	3.728**
Std Error			(1.670)	(1.568)

Notes: PPML estimates of theta. First two columns estimate theta using the migration response to a destination shock. Last two columns study the wage change as migrant flows increase -- the estimate of theta is the negative reciprocal of the coefficient reported in the last 2 rows. Migrant earnings and migrant flows are from the POEA/OWWA dataset. *** indicates significance at the 1% level. ** indicates significance at the 5% level * indicates significance at the 10% level.

Table A6: First Principal Component Loadings

Refrigerator	0.322

N	82	82	82	82
R2	0.427	0.842	0.403	0.655
Mean Dependent Variable	-0.000	-0.000	-0.014	-0.014

Notes: The outcome variables are indicated in the column headers, and are regressed on 1990 province characteristics. Robust standard errors. *** indicates significance at the 1% level. ** indicates significance at the 5% level * indicates significance at the 10% level.

Table A8: Impact of Migrant Earnings Shocks on Years of Schooling Completed

<i>Dependent variable: Years of schooling of...</i>	<i>Mean (std. dev.) of dependent variable</i>	<i>Regressions</i>		<i>Number of obs.</i>
		<i>(1) No controls</i>	<i>(2) Province-specific linear time trends</i>	
Children aged 7-18	4.880 (0.573)	0.680*** (0.187)	0.767*** (0.209)	328
Children aged 7-12	2.776 (0.332)	0.484*** (0.127)	0.484** (0.188)	328
Females	2.874 (0.331)	0.495*** (0.122)	0.506*** (0.174)	328
Males	2.684 (0.337)	0.473*** (0.134)	0.462** (0.207)	328
Children aged 13-15	6.401 (0.619)	0.342** (0.156)	0.269 (0.279)	328
Females	6.656 (0.601)	0.310** (0.155)	0.304 (0.281)	328
Males	6.157 (0.649)	0.375** (0.162)	0.242 (0.288)	328
Children aged 16-18	8.196 (0.951)	0.217 (0.259)	0.998 (0.759)	328
Females	8.621 (0.977)	0.221 (0.275)	1.167 (0.789)	328
Males	7.795 (0.943)	0.262 (0.264)	0.875 (0.752)	328
Young adults, aged 19-24	9.049 (1.109)	0.583** (0.239)	1.311*** (0.418)	328
Females	9.447 (1.137)	0.532** (0.263)	1.314*** (0.421)	328
Males	8.674 (1.104)	0.681*** (0.232)	1.383*** (0.440)	328

Notes: All regressions include province fixed effects, year fixed effects, baseline migrant earnings per capita times post, and weighted-average exchange rate shock times post. Regressions in column 2 include province-specific linear time trends. Average years of schooling are calculated from the 1990, 1995, 2000, and 2010 Philippine Censuses. Post equals 1 in 2000 and 2010, and 0 in 1990 and 1995. Robust standard errors are clustered at the province level. *** indicates significance at the 1% level. ** indicates significance at the 5% level * indicates significance at the 10% level.

Table A9: Falsification Tests (Test for Pretrends)

Fixed effects regressions. Columns 1 and 2 report coefficients (standard errors) on migrant earnings shock.				
Dependent variable	Mean (std. dev.) of dependent variable	Regressions		Number of obs.
		(1) No controls	(2) Controls for heterogeneous province trends	
(a) Years of Schooling				
Children aged 7-12	2.576 (0.270)	-0.233 (0.155)	-0.051 (0.180)	164
Females	2.666 (0.261)	-0.234 (0.154)	-0.037 (0.175)	164
Males	2.490 (0.283)	-0.233 (0.159)	-0.065 (0.189)	164
Children aged 13-15	6.155 (0.590)	-0.218 (0.223)	-0.041 (0.182)	164
Females	6.399 (0.554)	-0.313 (0.208)	-0.068 (0.186)	164
Males	5.921 (0.635)	-0.132 (0.245)	-0.005 (0.193)	164
Children aged 16-18	7.853 (0.920)	-0.540 (0.395)	-0.275 (0.341)	164
Females	8.244 (0.921)	-0.623 (0.406)	-0.261 (0.310)	164
Males	7.484 (0.935)	-0.446 (0.414)	-0.280 (0.401)	164
Young adults, aged 19-24	8.612 (1.047)	-0.394 (0.442)	-0.290 (0.330)	164
Females	8.955 (1.052)	-0.383 (0.496)	-0.260 (0.340)	164
Males	8.285 (1.061)	-0.394 (0.397)	-0.323 (0.343)	164
Share skilled in full population	0.196 (0.024)	0.0119 (0.0185)	-0.0024 (0.0199)	164
Share skilled migrants	0.302 (0.095)	0.120 (0.0759)	0.0826 (0.0969)	164
(b) Labor Supply				
Labor force participation, adults (age 25-64)	0.758 (0.075)	-0.035* (0.020)	-0.017 (0.029)	1693
Labor force participation, young adults (age 16-24)	0.545 (0.115)	0.041 (0.042)	-0.074 (0.086)	1693
Employment rate, children (age 10-15)	0.155 (0.134)	0.076* (0.046)	-0.059 (0.104)	1693

Notes: All regressions include province fixed effects, year fixed effects, baseline migrant earnings per capita times post, and weighted-average exchange rate shock times post. In panel (a), observations are at province/census-year level, for 1990 and 1995; post=1 if 1995, and 0 in 1990. In panel b, observations are at province-quarter level; "post" equals 1 in 1994 through 1997 quarter 2, and 0 otherwise. Controls for heterogeneous province trends are as follows: years of schooling (panel a), baseline controls as included in Table 3; for labor supply outcomes (panel b), province-specific linear time trends. Robust standard errors are clustered at the province level. *** indicates significance at the 1% level. ** indicates significance at the 5% level * indicates significance at the 10% level.

Table A10: Impact of Migrant Earnings Shocks on Adult Domestic Employment Rates

Fixed effects regressions. Columns 1 and 2 report coefficients (standard errors) on migrant earnings shock. Data from each of 77 provinces over 80 quarters (Q1 1992 - Q4 2011).

<i>Dependent variable</i>	<i>Mean (std. dev.) of dependent variable</i>	<i>Regressions</i>		<i>Number of obs.</i>
		<i>(1)</i> <i>No controls</i>	<i>(2)</i> <i>Province-specific linear time trends</i>	
Employment rate, adults (age 25-64)	0.737 (0.075)	-0.0588* (0.0338)	0.0296 (0.0407)	6159
Females	0.565 (0.129)	-0.0686 (0.0586)	0.0601 (0.0720)	6159
Males	0.910 (0.051)	-0.0418* (0.0218)	-0.0004 (0.0185)	6159
Employment rate, young adults (age 16-24)	0.452 (0.108)	-0.0222 (0.0661)	-0.0377 (0.0533)	6159
Females	0.308 (0.114)	-0.0297 (0.1000)	-0.0139 (0.0623)	6159
Males	0.576 (0.134)	-0.0181 (0.0600)	-0.0388 (0.0503)	6159

Notes: All regressions include province fixed effects, year fixed effects, baseline migrant earnings per capita times post, and weighted-average exchange rate shock times post. Regressions in column 2 include province-specific linear time trends. Employment outcome data are from the Philippine Labor Force Survey, and cover the years 1992-2011. The unit of observation is the province/quarter. Employment rate is share working out of total population in age group. International migrants are excluded in calculation of outcome variables. Post equals 1 in 1997, quarter 3 to 2011, and 0 in 1992-1997, quarter 2. Robust standard errors are clustered at the province level. *** indicates significance at the 1% level. ** indicates significance at the 5% level * indicates significance at the 10% level.

Table A11: Impact of Migrant Earnings Shocks on Internal Migration

Fixed effects regressions. Columns 1 and 2 report coefficients (standard errors) on migrant earnings shock.

Data from each of 77 provinces over three periods (1990, 2000, 2010).

<i>Dependent variable:</i> <i>Internal Migration</i>	<i>Mean (std. dev.) of dependent variable</i>	<i>Regressions</i>		<i>Number of obs.</i>
		<i>(1)</i> <i>No controls</i>	<i>(2)</i> <i>Province-specific linear time trends</i>	
Immigration rate				
Aged 25-64	0.029 (0.022)	0.071** (0.032)	0.054 (0.053)	231
Aged 16-24	0.035 (0.029)	0.099*** (0.036)	0.048 (0.052)	231
Aged 7-12	0.022 (0.017)	0.061* (0.031)	0.043 (0.044)	231
Aged 13-15	0.021 (0.018)	0.077*** (0.029)	0.053 (0.039)	231
Outmigration rate				
Aged 25-64	0.030 (0.024)	-0.018 (0.025)	-0.056 (0.041)	231
Aged 16-24	0.046 (0.036)	-0.044 (0.034)	-0.079 (0.057)	231
Aged 7-12	0.021 (0.019)	-0.011 (0.019)	-0.030 (0.040)	231
Aged 13-15	0.022 (0.020)	-0.019 (0.019)	-0.039 (0.034)	231
Net migration rate				
Aged 25-64	0.000 (0.025)	-0.089* (0.046)	-0.111 (0.078)	231
Aged 16-24	0.011 (0.043)	-0.143*** (0.053)	-0.127 (0.090)	231
Aged 7-12	-0.001 (0.020)	-0.072* (0.042)	-0.074 (0.072)	231
Aged 13-15	0.001 (0.022)	-0.096** (0.038)	-0.092 (0.064)	231

Notes: All regressions include province fixed effects, year fixed effects, baseline migrant earnings per capita times post, and weighted-average exchange rate shock times post. Regressions in column 2 include province-specific linear time trends. Internal migration rates are calculated from the 1990, 1995, 2000, and 2010 Philippine Censuses. There are 77 provinces per year rather than the 82 shown in the other tables using Census data due to corrupt internal migration data for five provinces in 1990. At the recommendation of the PSA, we have dropped these 5 provinces in all years. Net migration rate is outmigration rate minus immigration rate. Post equals 1 in 2000 and 2010, and 0 otherwise. Robust standard errors are clustered at the province level. *** indicates significance at the 1% level. ** indicates significance at the 5% level * indicates significance at the 10% level.
